Learning Objective 1

Recognize the role of genes in predicting treatment response, and prevention of disease progression in mood and anxiety disorders.

Learning Objective 2

Identify clinical and biological factors predictive of treatment outcomes in major depressive disorder (MDD).

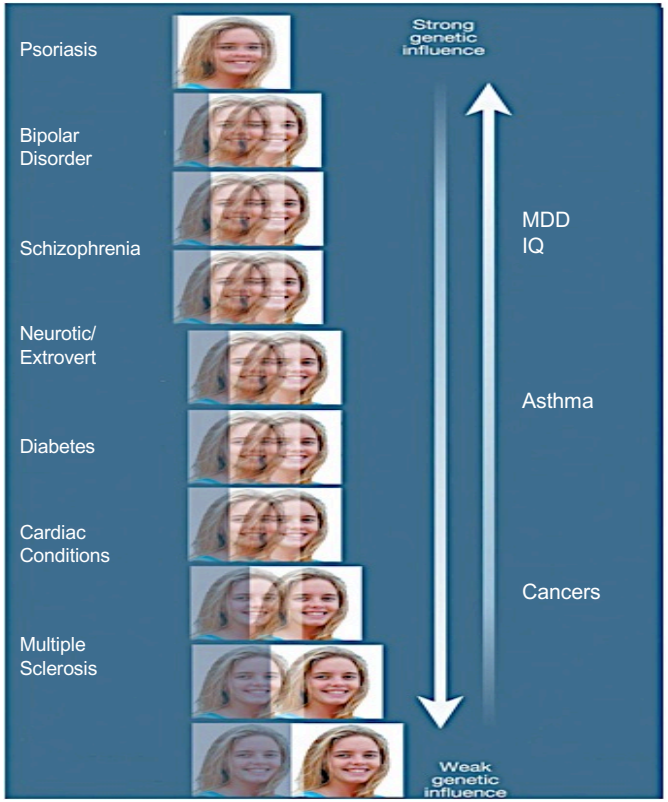
Nature, Nurture, and Human Disease



***"We used to think our fate was in our stars. Now we know, in large measure, our fate is in our genes."* J. D. Watson**

Studies of identical twins have revealed that some conditions, such as psoriasis, have a strong genetic component and are less influenced by environmental and lifestyle factors — identical twins are more likely to share these diseases. But other conditions, such as multiple sclerosis, are only weakly influenced by genetic makeup and therefore twins may show differences depending on their exposure to various environmental factors.

Chakravarti A, et al. *Nature*. 2003;421:412-414.

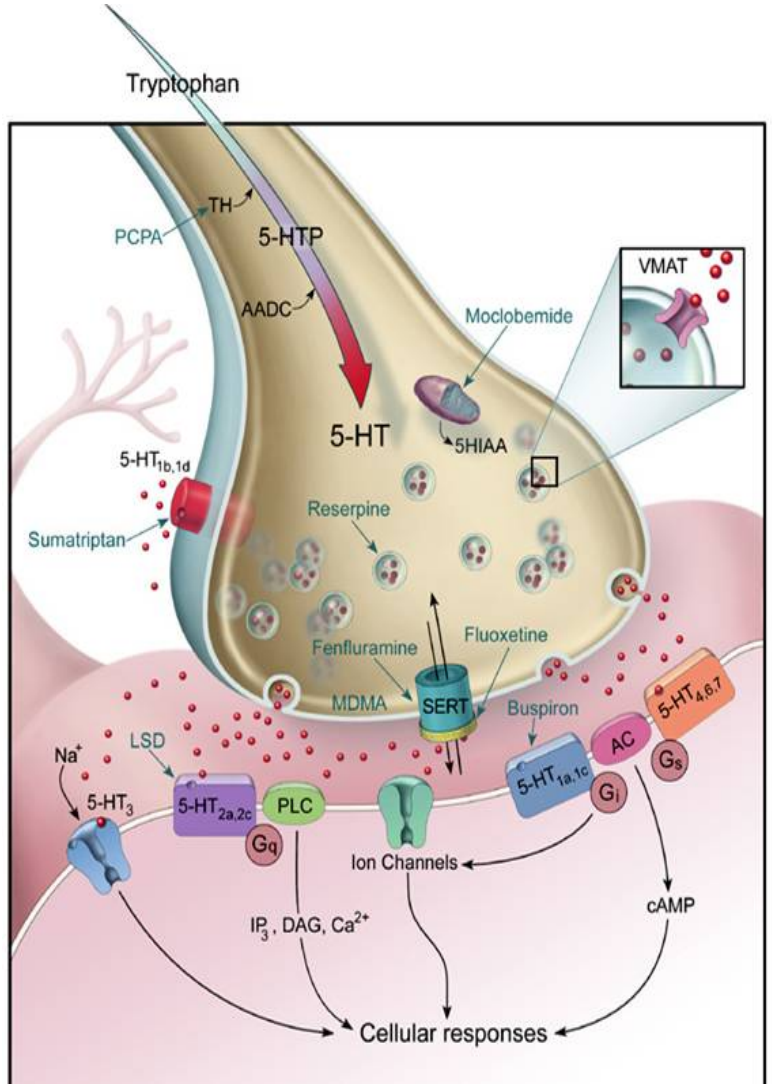
Neurotransmitters and Depression

- There are disturbances in the monoamine systems
  - serotonin (5-hydroxytryptamine, 5-HT)
  - norepinephrine (NE)
  - dopamine (DA)?
- There are also disturbances in other neurotransmitter systems
  - e.g., corticotropin-releasing factor [CRF] and substance P
- Serotonin and norepinephrine have been the most extensively studied in the clinical setting



Tryptophan
TH
PCPA
5-HTP
AADC
VMAT
Moclobemide
5-HT
5HIAA
5-HT1b,1d
Sumatriptan
Reserpine
Fenfluramine
Fluoxetine
MDMA
SERT
Buspiron
5-HT4,6,7
AC
Gs
Na+
LSD
5-HT3
5-HT2a,2c

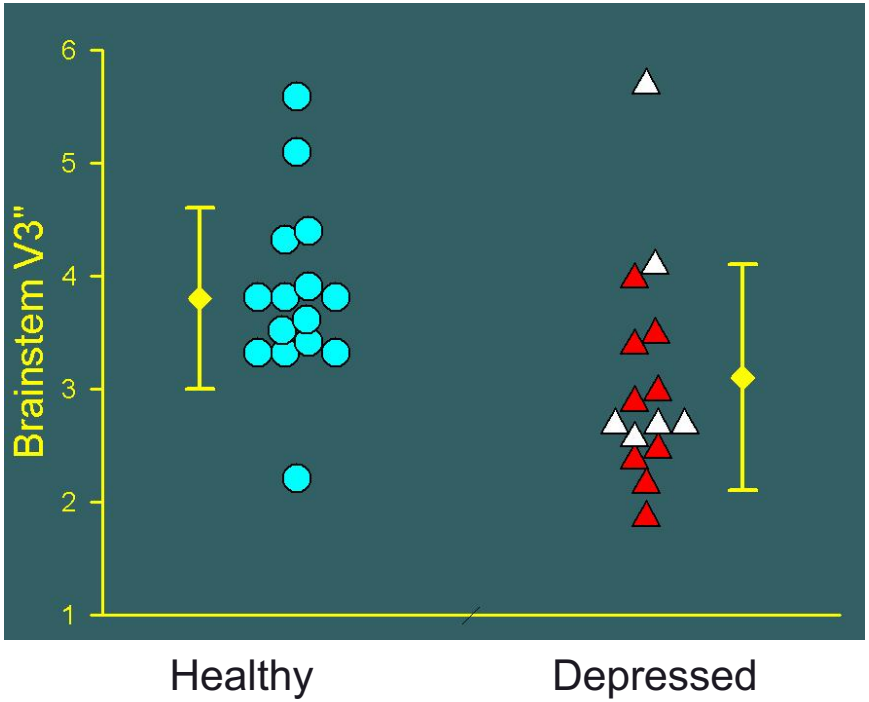
5-HT1a,1c
Gi
Ion Channels
cAMP
IP3, DAG, Ca2+
Cellular responses

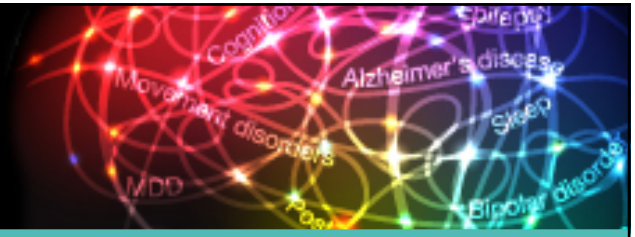
Reduced Brainstem [123I]β-CIT Binding in Depression



*p = 0.03

Malison RT, et al. *Biol Psychiatry* 1998;44(11):1090-1098.

Dopamine and Depression

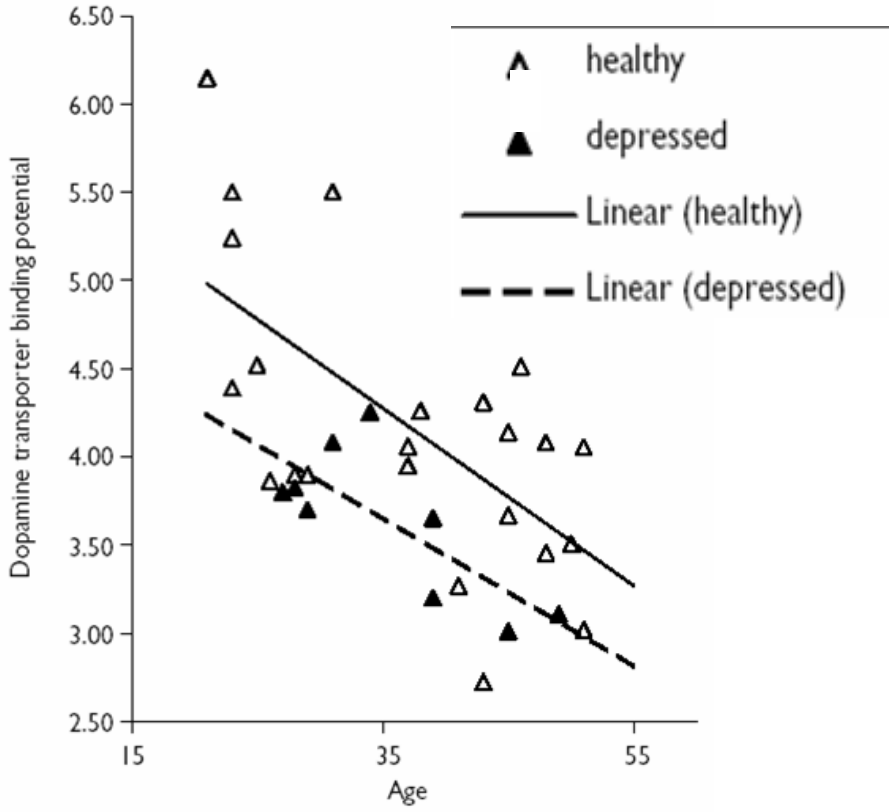


- Role of dopamine neurons in behavioral and physiological areas altered in depression
- High rate of comorbidity of Parkinson's disease and depression
- Pathophysiological involvement of DA systems in depression

Imaging Studies Postmortem Studies Biological Fluids Studies

- Role of DA circuits in the actions of antidepressants
  - MAOIs
  - Effects on the DA transporter

Lower Dopamine Tranporter Binding Potential in Striatum During Depression



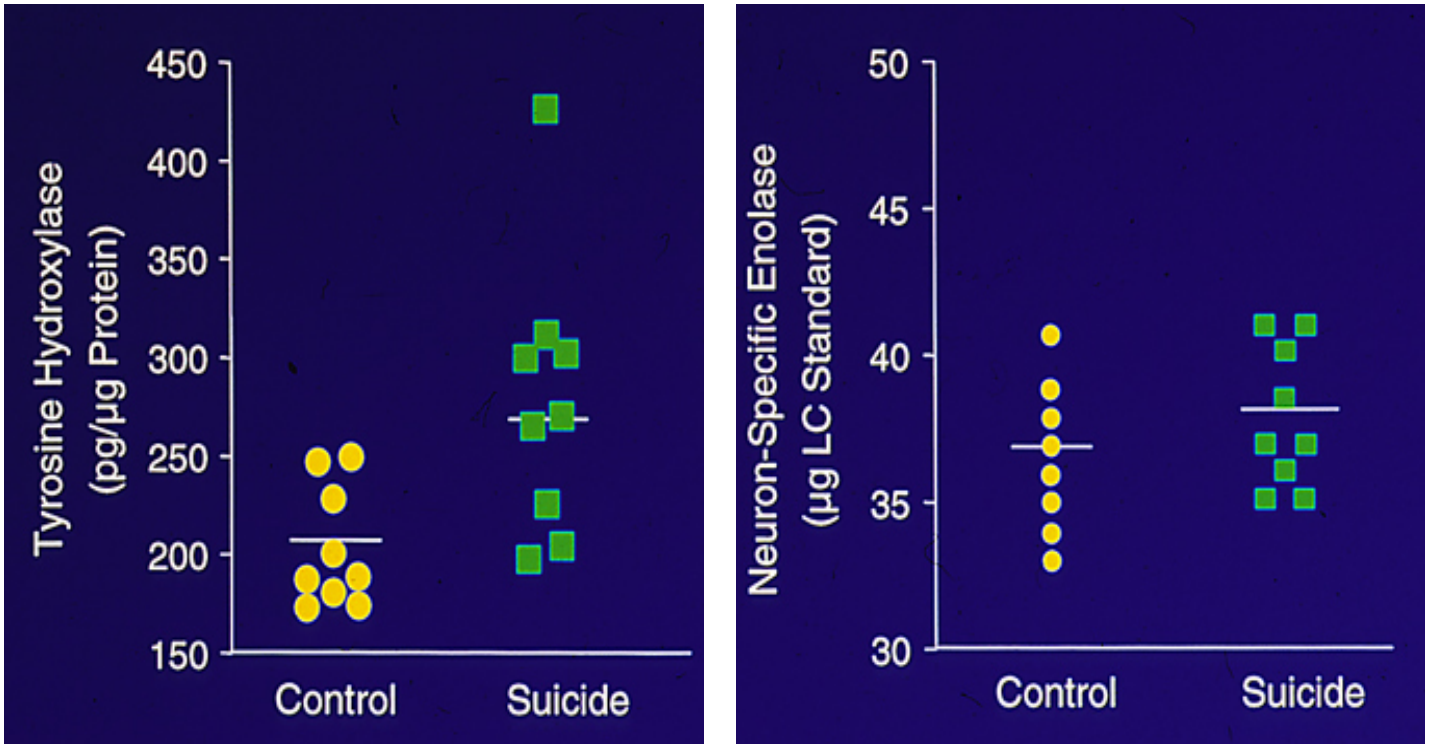
Dopamine transporter binding potential in bilateral striatum is lower in depressed patients. Data was analyzed using analysis of covariance with age as a covariate, examining effect of diagnosis (effect of diagnosis: $F_{1,29} = 7.1$, $p = 0.01$).

Meyer JH, et al. *Neuroreport*. 2001;12(18):4121-4125.

Norepinephrine Alterations

- NE dysfunction is linked to depression
  - Low levels of NE metabolites are found in the urine and CSF of depressed patient
  - Increased density of β-adrenergic receptors is found at postmortem in the cortex of depressed suicide victims
  - NE reuptake inhibitors are effective antidepressants
    - desipramine, reboxetine, maprotiline

TH and NSE Levels in Sections of LC from Control and Suicide Victims



TH = tyrosine hydroxylase, NSE = neuron specific enolase, LC = locus coeruleus

Ordway GA, et al. *J Neurochem*. 1994;62(2):680-685.

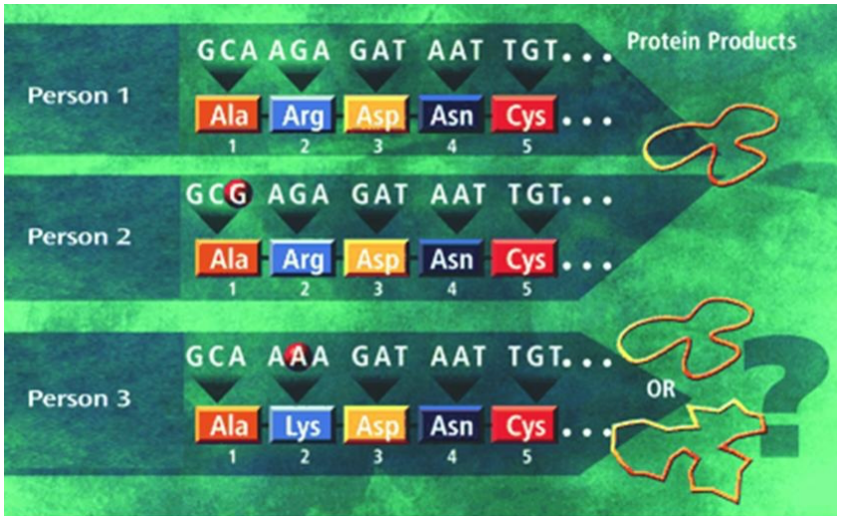
DNA Sequence Variation Can Change the Protein Produced by the Genetic Code



This image shows how DNA sequence variation in a gene can change the protein produced by the genetic code. The nucleotide triplet codon at position 1 in the gene depicted is different in person 1 and person 2, but the codon difference does not change the amino acid sequence. In person 3, the nucleotide triplet codon at position 2 is different from that in person 1 and person 2, and the codon change results in production of a different amino acid at position 2 in person 3.

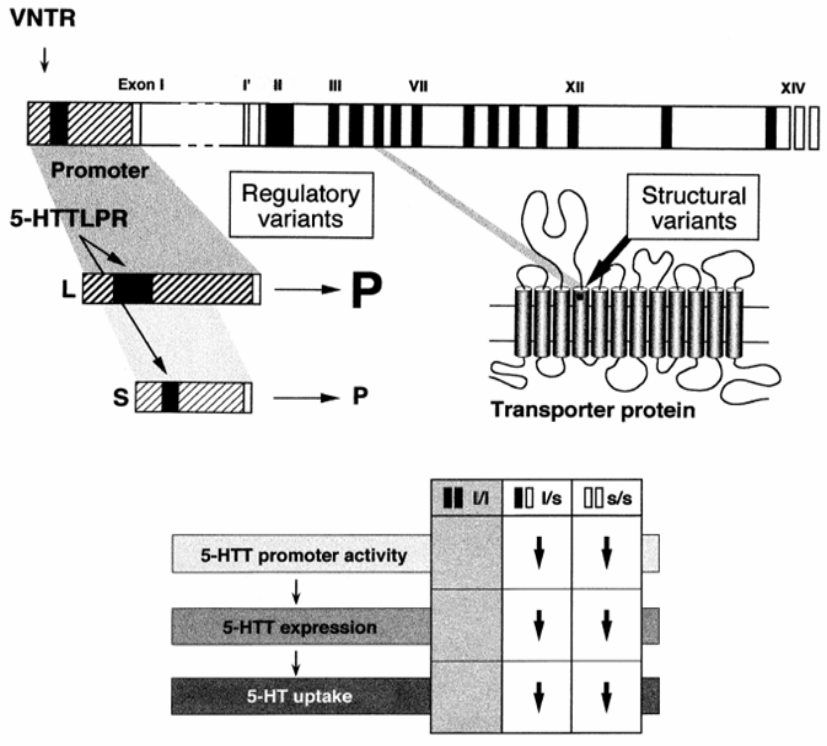
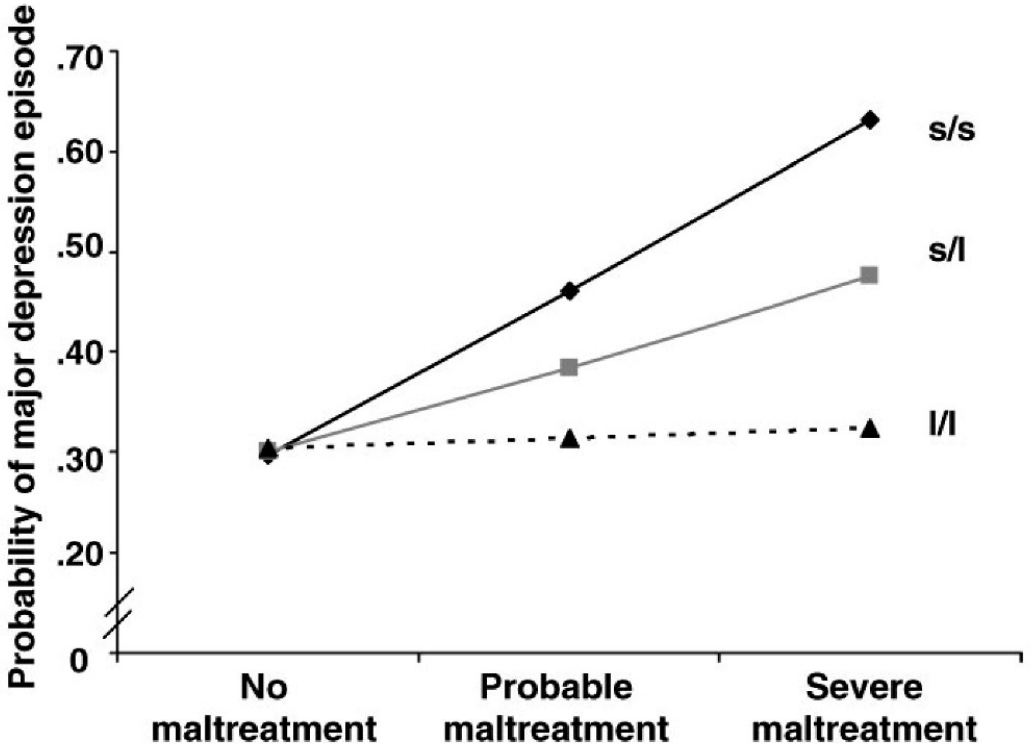
5’-HT Transporter Promoter Polymorphism (SLC6A4, 17q11)



Adapted from Lesch KP, *Mossner R. Biol Psychiatry*. 1998;44(3):179-192.

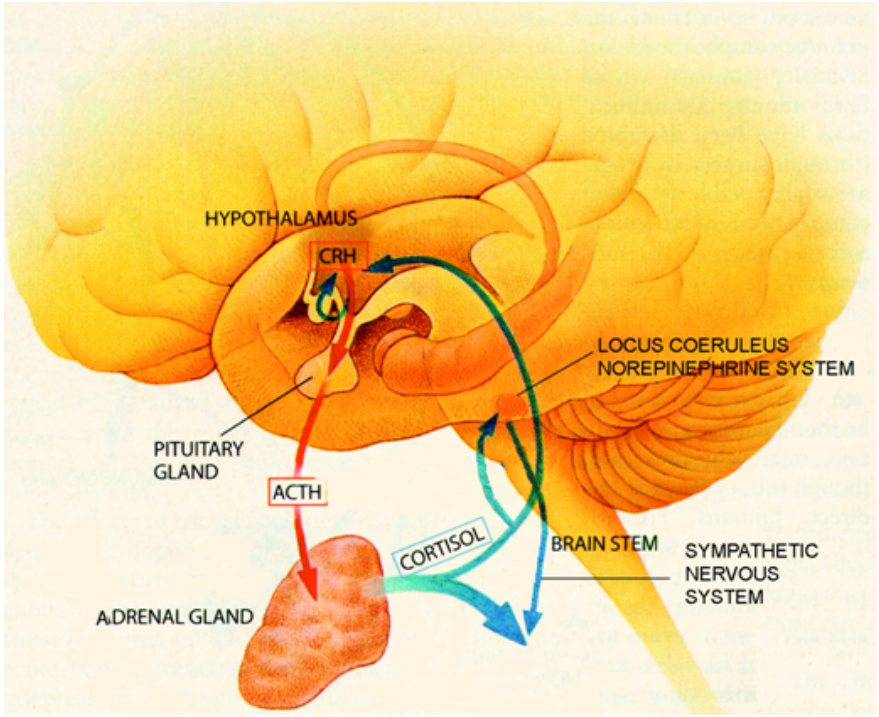
Results of Regression Analysis

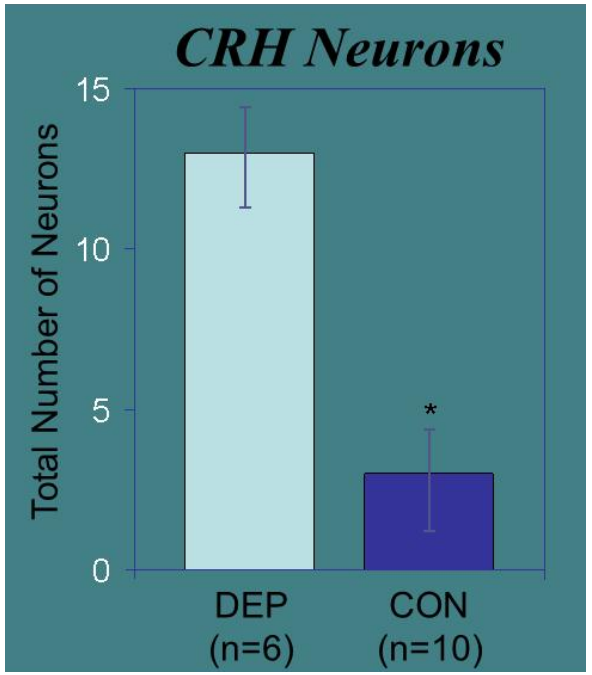
- Estimating the association between childhood maltreatment (between the ages of 3 and 11yrs) and adult depression (ages 18 to 26), as a function of 5-HTT genotype



Caspi A, et al. *Science*. 2003;301(5631):386-389.

Regulation of Stress Response by CRH and HPA Axis



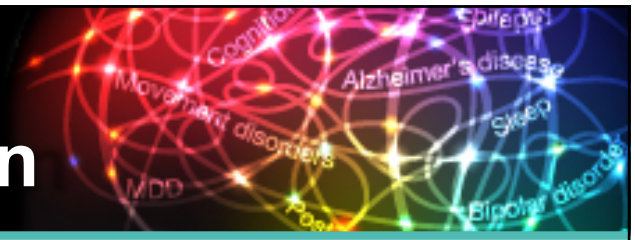


*p < .01; mean ± SEM

HPA = hypothalamic-pituitary-adrenal; ACTH = adrenocorticotropic hormone; DEP = depressed patients; CON = control patients

Purba JS, et al. *Neuroendocrinology*. 1995;62(1):62-70.; Raadsheer FC, et al. *Neuroendocrinology*. 1994;60:436-444.

Central CRH:
A Mediator of Stress and Depression



- CRH CSF concentrations are elevated in depression
- CRH stimulation test shows blunted ACTH response in depression
- Combined dexamethasone/CRH stimulation test is dysregulated in depression
- Increased pituitary/adrenal gland size in depression
- In animals, CRF injections into brain mimic anxiety and chronic depression
- These effects can be blocked by CRHR1 antagonists and a neurokinin-2 (NK2) receptor antagonist
- A principle source of brain CRH is the central nucleus of the amygdala, known to be involved in stress response and depression

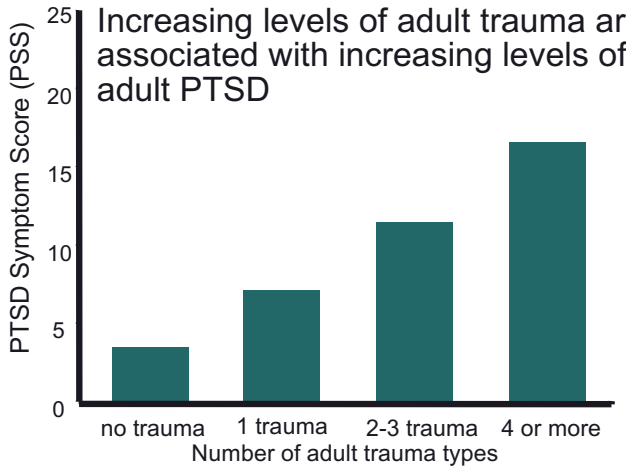
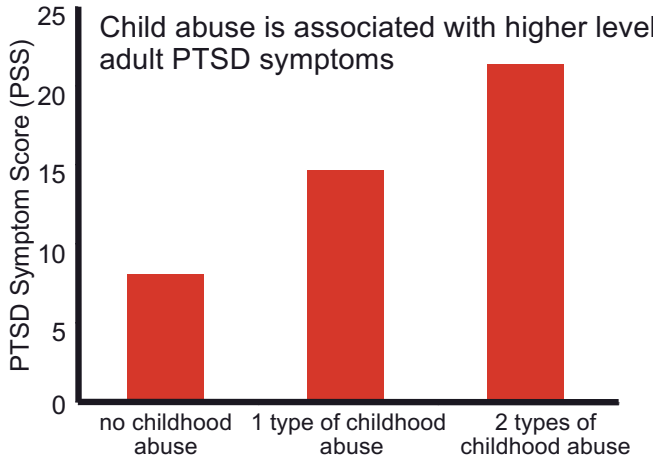
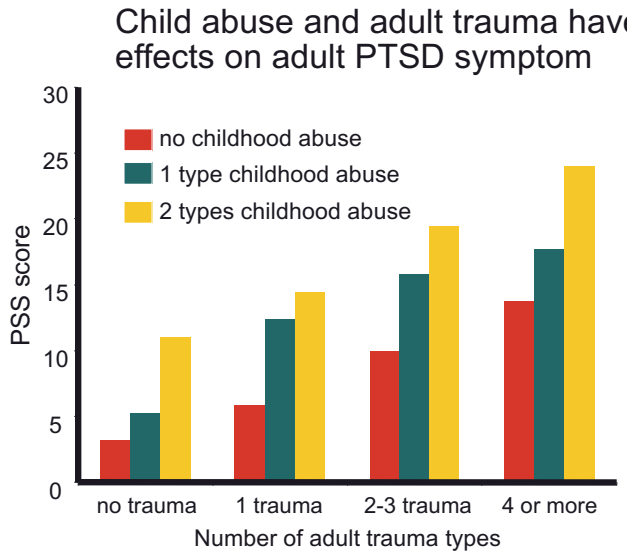
Adult Trauma and Child Abuse Predict PTSD

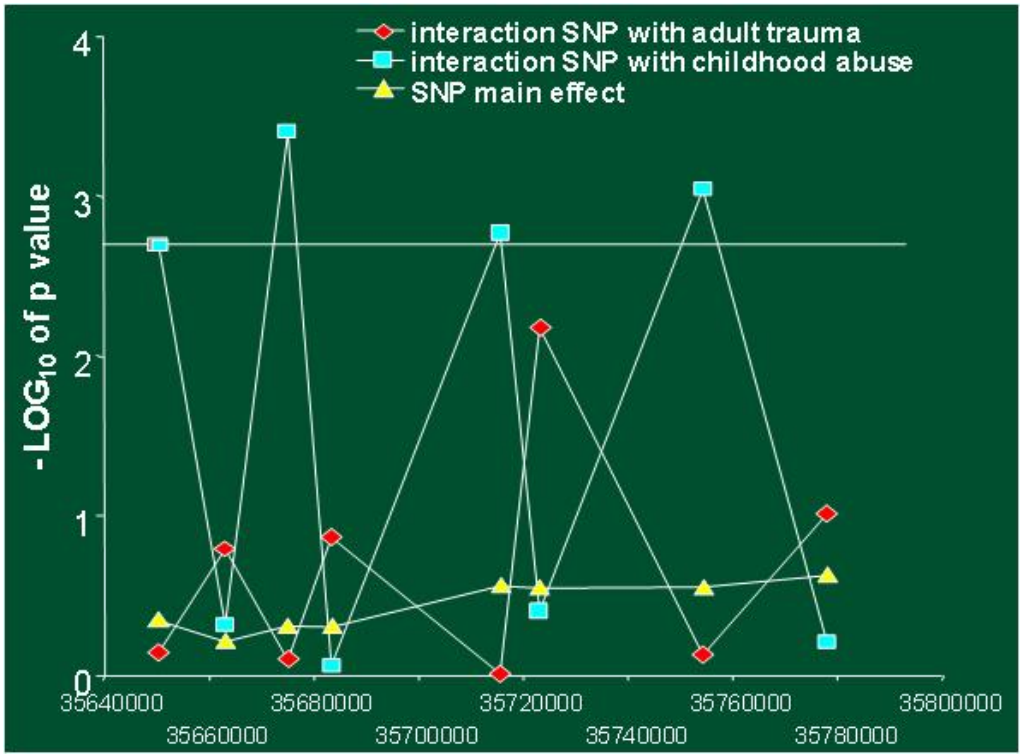


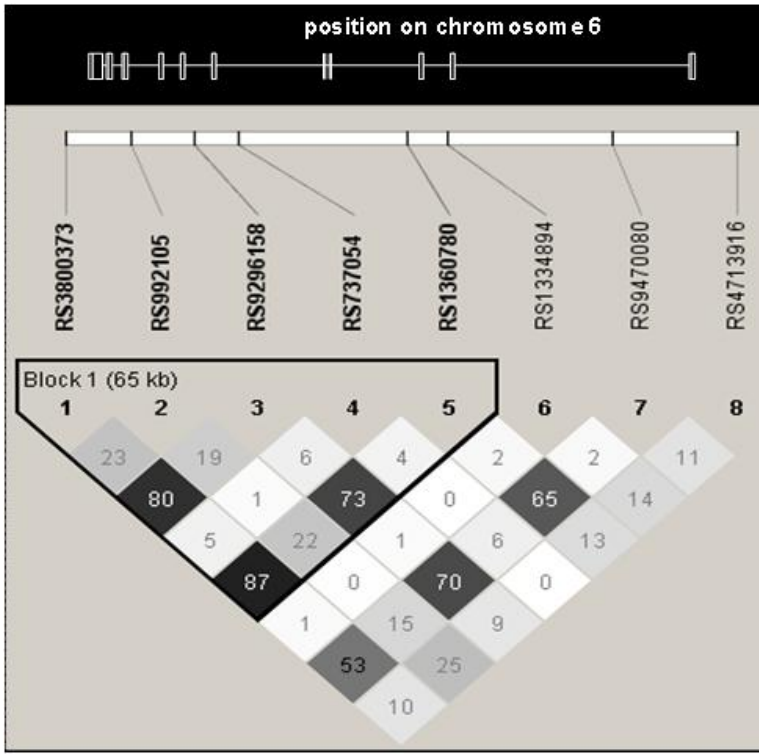




Binder EB, et al. *JAMA*. 2008;299:1291-1305.

FKBP5 SNPs and Main Genetic Effect on PTSD Symptoms and Interaction Effects with Adult Trauma Levels and Child Abuse

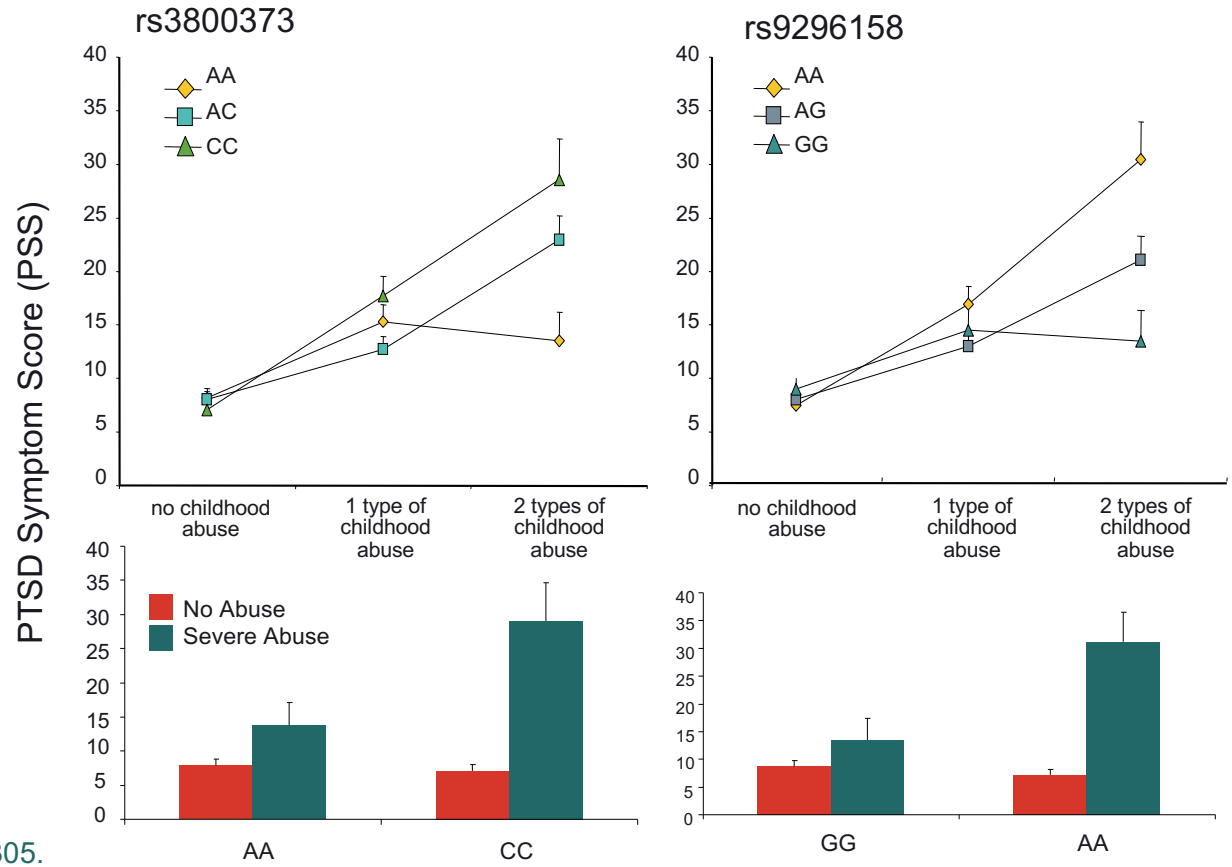




Binder EB, et al. *JAMA*. 2008;299(11):1291-1305.

PTSD Severity, FKBP5 SNP Genotypes and Child Abuse

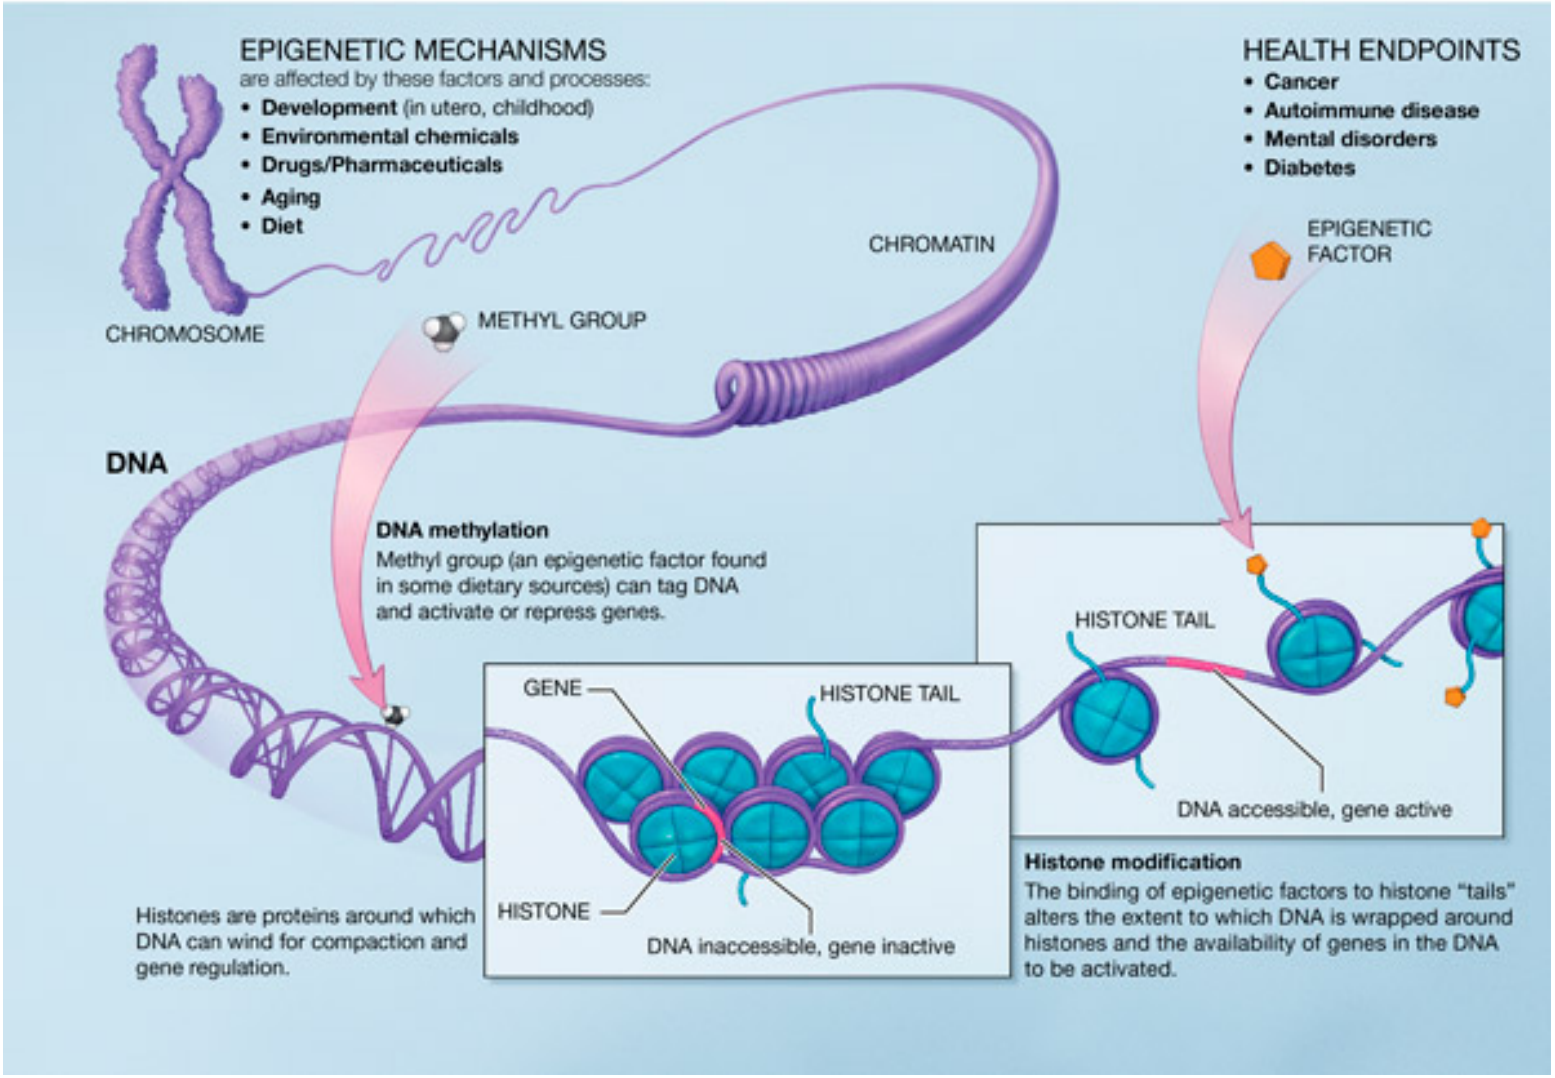
For all 4 SNPs *(rs1360780 and rs9470080 not shown)* an additive interaction effect with child abuse on PSS score is observed



Binder EB, et al. *JAMA*. 2008:299:1291-1305.

Epigenetics

- The phenomenon of heritable (‘metastable’) changes in gene regulation that are governed by non-Mendelian processes, primarily through biochemical modifications to chromatin structure that occur during life.



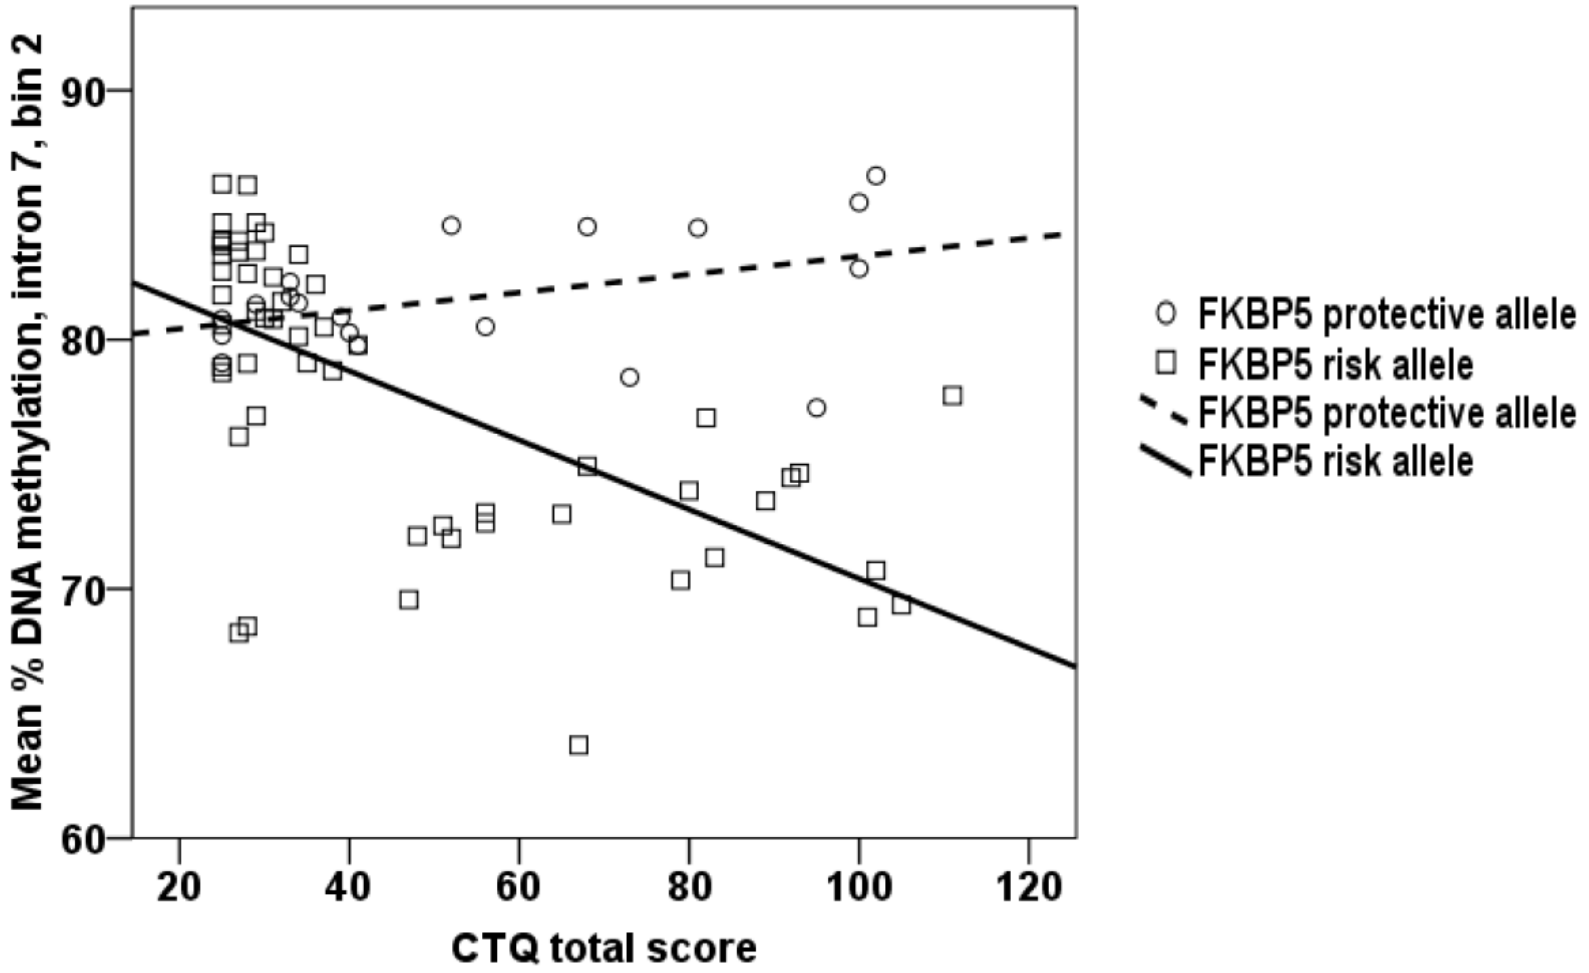
EPIGENETIC MECHANISMS
are affected by these factors and processes:
• Development (in utero, childhood)
• Environmental chemicals
• Drugs/Pharmaceuticals
• Aging
• Diet
HEALTH ENDPOINTS
• Cancer
• Autoimmune disease
• Mental disorders
• Diabetes
CHROMOSOME
CHROMATIN
METHYL GROUP
EPIGENETIC FACTOR
DNA
DNA methylation
Methyl group (an epigenetic factor found in some dietary sources) can tag DNA and activate or repress genes.
GENE
HISTONE TAIL
HISTONE
DNA inaccessible, gene inactive
HISTONE TAIL
DNA accessible, gene active
Histones are proteins around which DNA can wind for compaction and gene regulation.
Histone modification
The binding of epigenetic factors to histone "tails" alters the extent to which DNA is wrapped around histones and the availability of genes in the DNA to be activated.

Allele-Specific DNA Demethylation in FKBP5: A Molecular Mediator of Gene X Childhood Trauma Interactions

Torsten Klengel, Divya Mehta, Christoph Anacker, Jens C. Pruessner, Carmine M. Pariante, Thaddeus W.W. Pace, Kristina B. Mercer, Helen S. Mayberg, Bekh Bradley, Charles B. Nemeroff, Florian Holsboer, Christine M. Heim, Kerry J. Ressler, Theo Rein, and Elisabeth B. Binder

A polymorphism in the FK506 binding protein 5 (*FKBP5*) gene, an important regulator of the stress hormone system, increase the risk of developing stress-related psychiatric disorders in adulthood by allele-specific, childhood trauma-dependent DNA demethylation in functional glucocorticoid response elements (GREs) of *FKBP5*. This demethylation is linked to increased stress-dependent gene transcription followed by a long-term dysregulation of the stress hormone system and a global impact on the function of immune cells and brain areas associated with stress regulation.

Klengel T, et al. *Nat Neurosci*. 2013;16(1):33-41.



Klengel T, et al. *Nat Neuroci*. 2013;16(1):33-41.

ADCYAP1R1 Associated with PTSD in Females

Only the *ADCYAP1R1* receptor SNP rs2267735 remained significant after experiment correction for sex and 44 independent tests

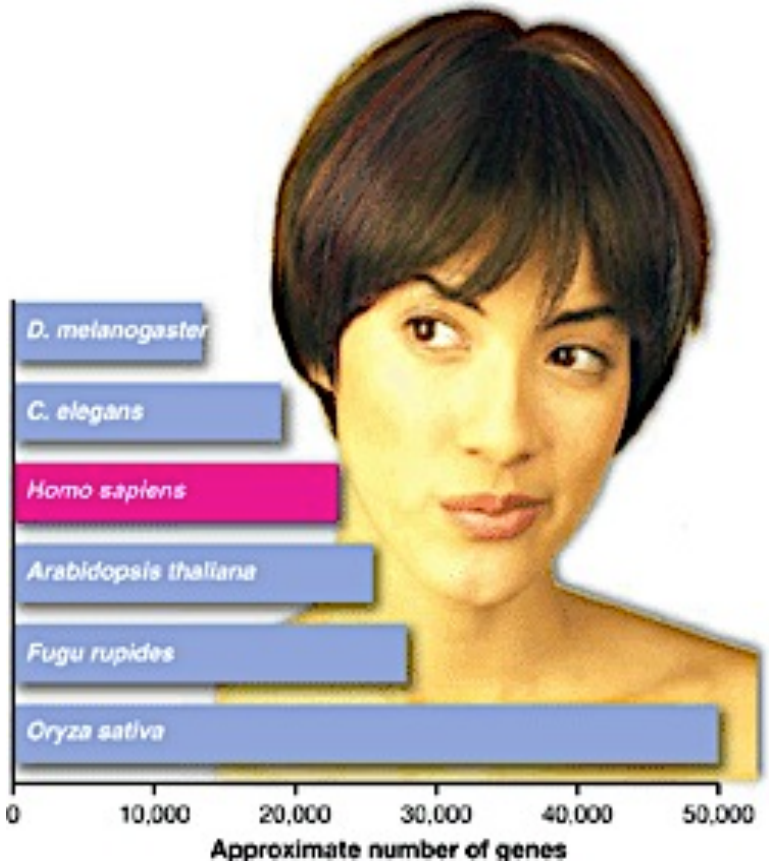
Biggest Surprise From the Genome Projects: Number of Conventional Genes Do Not Scale with Complexity

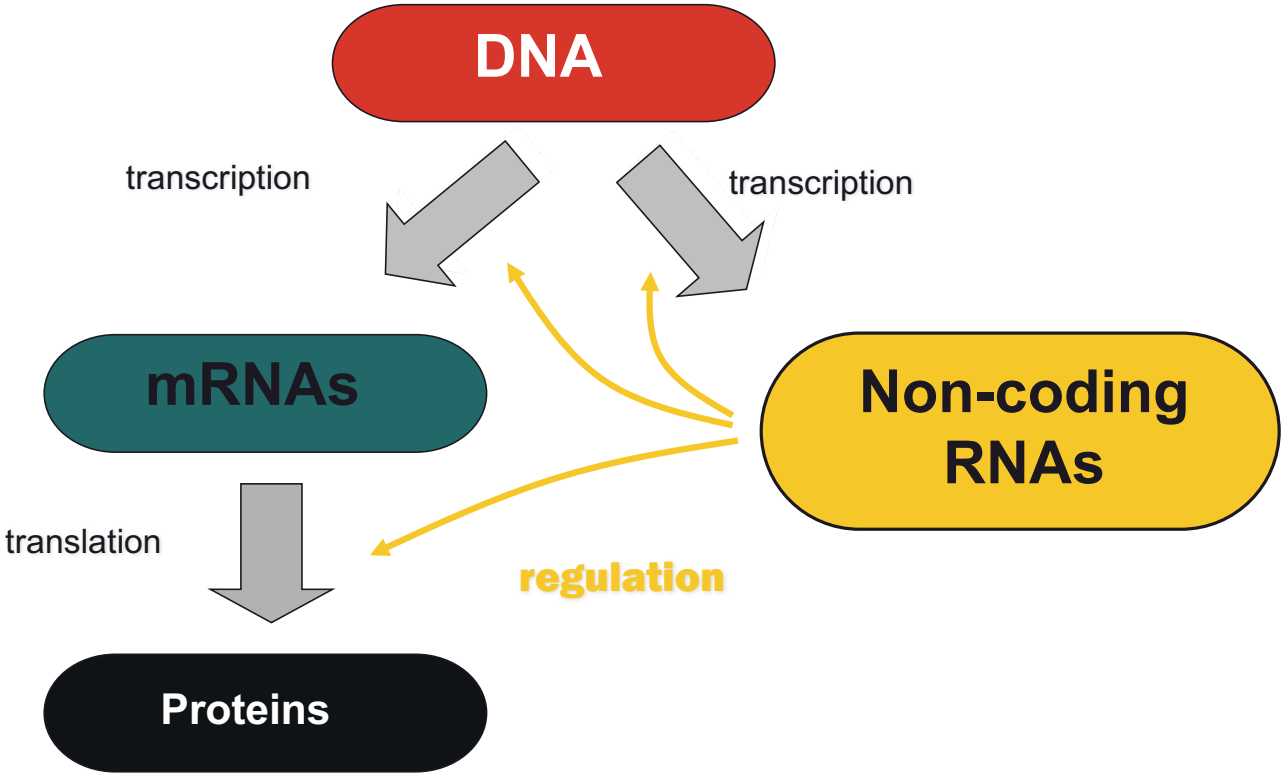


Daiger, SP. *Science*. 2005;362-364.

Where is the Information That Programs Our Complexity?

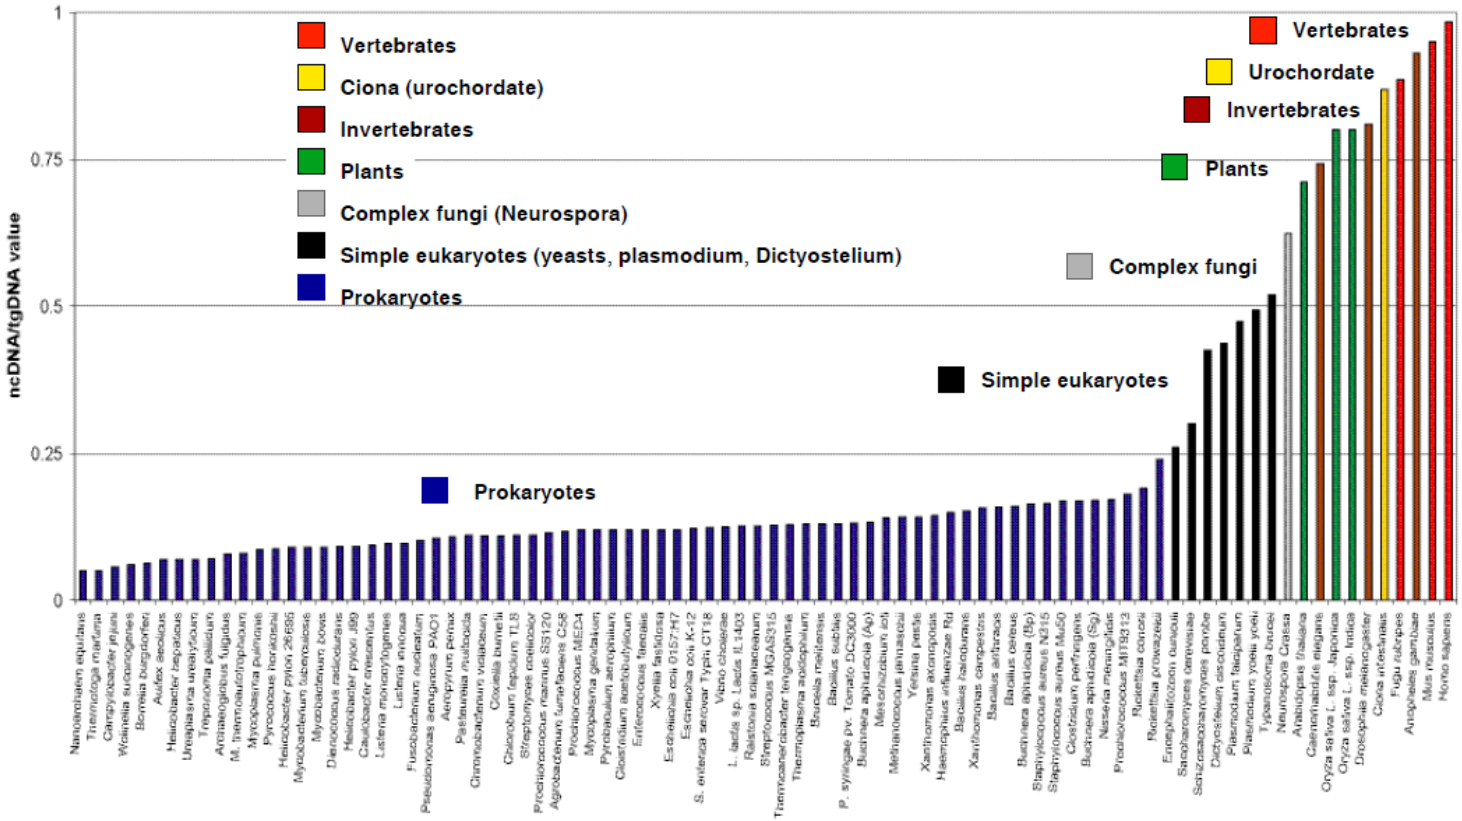
Modified “Central Dogma”

F. Crick

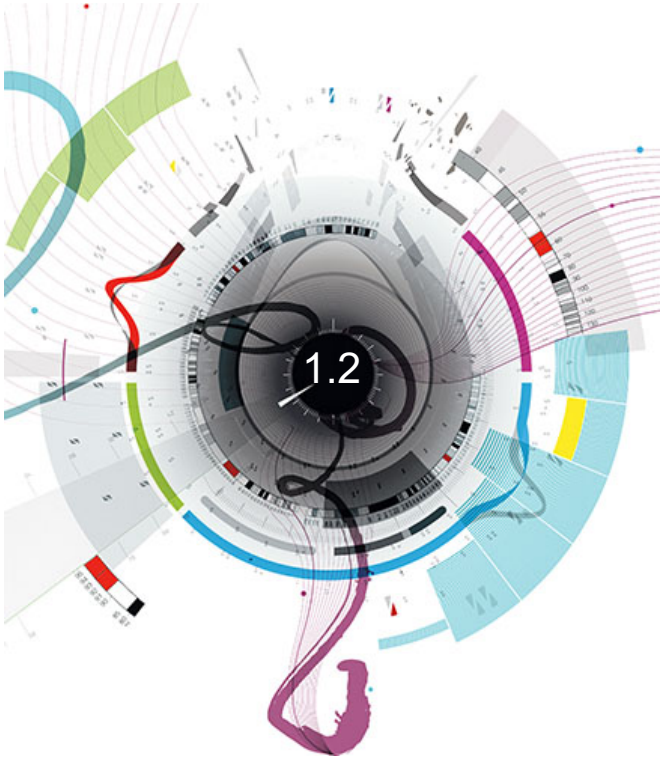


The Proportion of Nancoding DNA Broadly Increases with Developmental Complexity

J. Mattick



Only 1.2% of the Genome is Made Up of Conventional Genes…



…but most of the genome is transcribed.

Zimmer C. *New York Times*, November 10, 2008. http://www.nytimes.com/2008/11/11/science/11gene.html?_r=0.

New View of the Human Genome

- Islands of (conventional) protein-coding genes in a sea of regulatory information
- “Genes” are not discrete entities
- Regulation is orchestrated by RNA as well as proteins
- Theory: Complexity is achieved primarily by RNA

Why Study microRNAs in Psychiatric Disease?

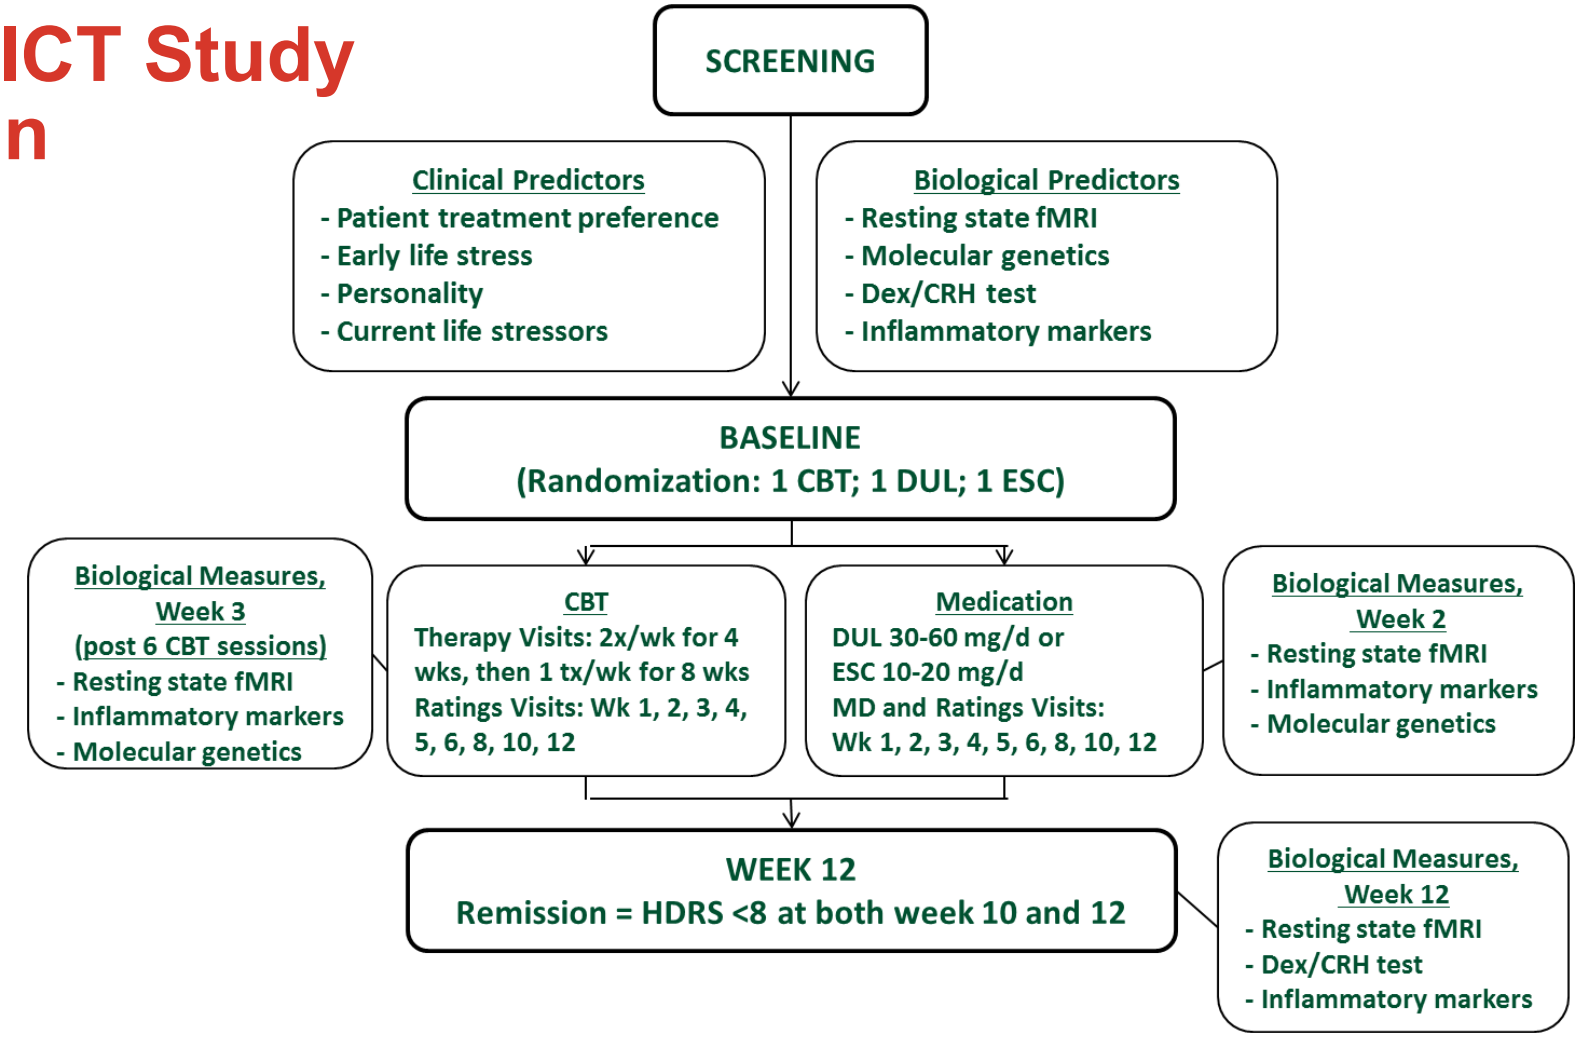
- MicroRNAs are predicted to regulate up to hundreds of genes each (‘master regulators’)
- At least half of protein-coding genes may be regulated by microRNAs
- Single microRNAs may target multiple genes within a biological pathway
- MicroRNAs evolve easily and their number increases with organismal complexity
- Major role in neurodevelopment and cell differentiation
- Regulatory layer that may account for missing genetic/epigenetic variability in the etiology of disease

Predictors of Remission in Depression to Individual and Combined Treatments [PReDICT]

- PReDICT study aimed to identify clinical and biological factors predictive of treatment outcomes in major depressive disorder (MDD) among treatment naïve adults.
- The authors evaluated the efficacy of cognitive behavioral therapy (CBT) and 2 antidepressant medications (escitalopram and duloxetine) in patients with major depression and examined the moderating effect of patients' treatment preferences on outcomes.

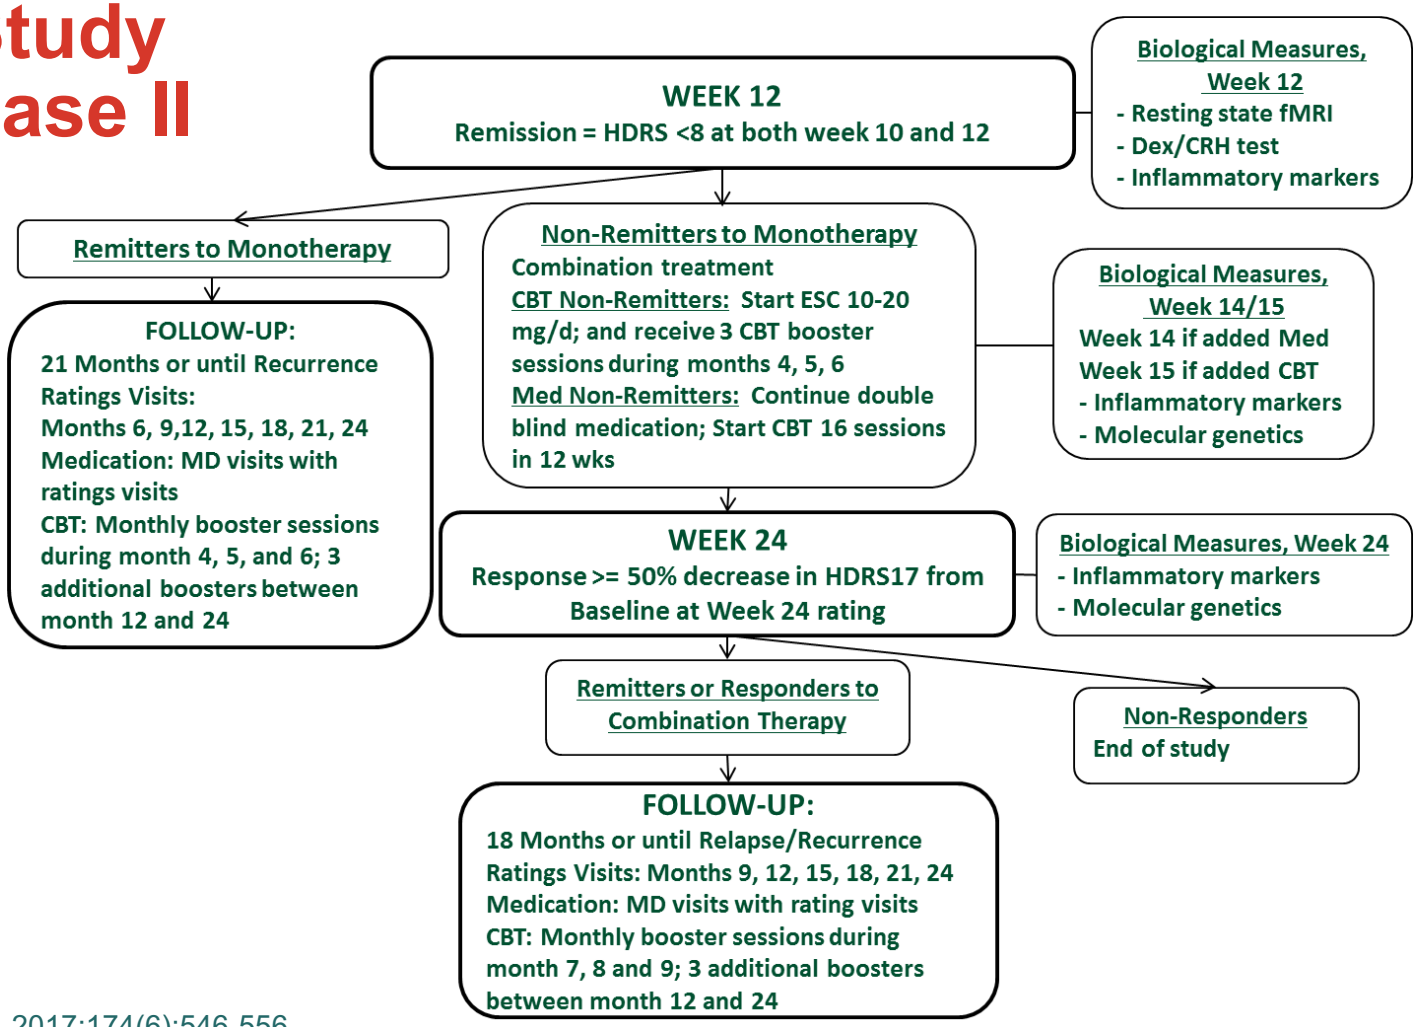
Dunlop B, et al. *Am J Psychiatry*. 2017;174(6):546-556.

PReDICT Study Design



Dunlop B, et al. *Am J Psychiatry*. 2017;174(6):546-556.

PReDICT Study Design, Phase II



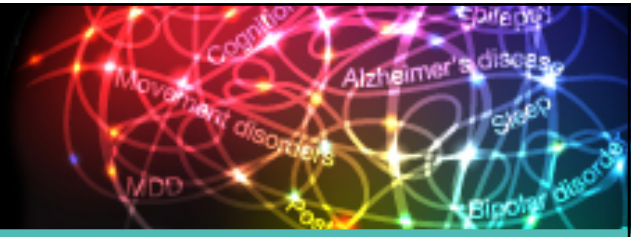
Dunlop B, et al. *Am J Psychiatry*. 2017;174(6):546-556.

PReDICT Methods

- Adults aged 18-65 with treatment-naïve MDD were randomly assigned with equal likelihood to 12 weeks of treatment with escitalopram (10-20 mg/day), duloxetine (30-60 mg/day), or CBT (16 x 50-minute sessions).
- Prior to randomization, patients indicated whether they preferred medication or CBT or had no preference
- The primary outcomes was change in the 17-item Hamilton Depression Rating Scale (HAM-D), administered by raters blinded to treatment.

Dunlop B, et al. *Am J Psychiatry*. 2017;174(6):546-556.

PReDICT Results



- A total of 344 patients were randomly assigned, with a mean baseline HAM-D score of 19.8 (SD = 3.8)
- The mean estimated overall decreases in HAM-D score did not significanty differ between treatments
  - CBT: 10.2
  - Escitalopram: 11.1
  - Duloxetine: 11.2
- Last observation carried forward remission rates did not significantly differ between treatments
  - CBT: 41.9%
  - Escitalopram: 46.7%
  - Duloxetine: 54.7%
- Patients matched to their preferred treatment were more likely to complete the trial but not more likely to achieve remission

Dunlop B, et al. *Am J Psychiatry*. 2017;174(6):546-556.

Modeled Change in the Mean Hamilton Depression Rating Scale (HAM-D) Score by Week

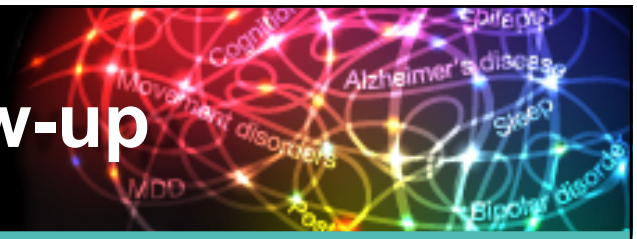
Kennedy et al. 2017

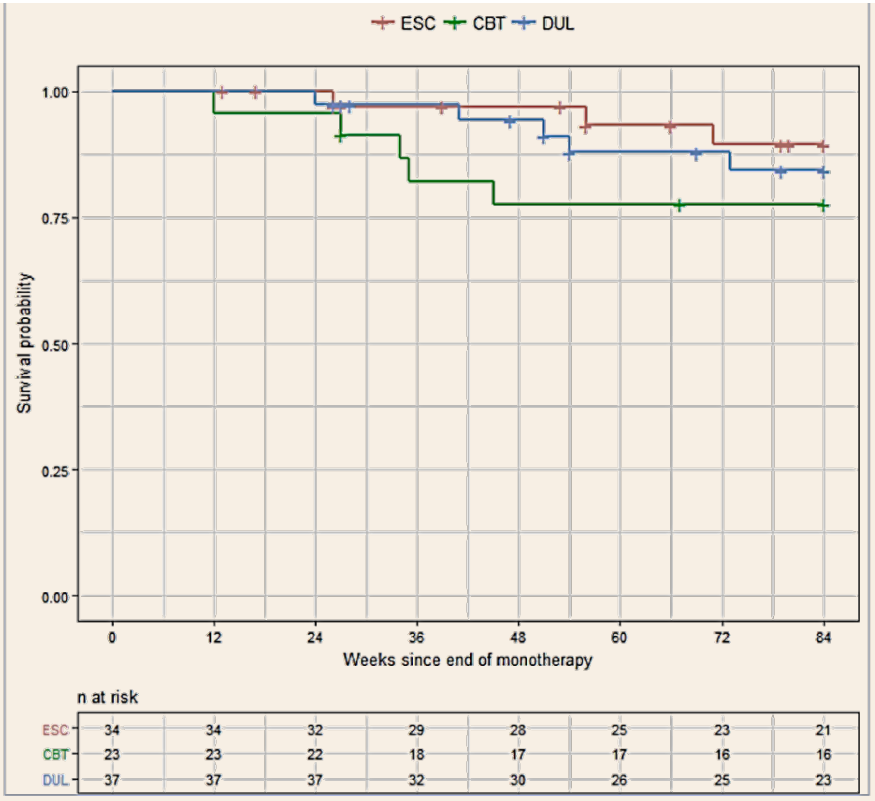
Monotherapy Remitter 2-Year Follow-up



- No differences in three treatments for 94 (109) who remitted to monotherapy
- Relapse rate was ~15%
- Two variables predicted relapse
  - Residual symptoms of depression
  - Baseline diagnosis of comorbid anxiety
- Will be investigating biomarkers of recurrence.

Kennedy et al., 2017.

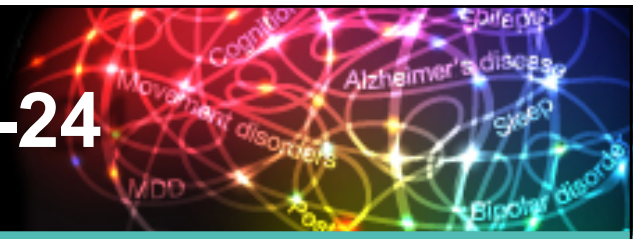
Cumulative Proportion of Participants Surviving Without Depressive Relapse/Recurrence Over 21 Months of Follow-up



Note. ESC = escitalopram; CBT = cognitive behavior therapy; DUL = duloxetine

Kennedy et al., 2017.

Combination Treatment – Weeks 12-24



- No differences at 24 weeks in three combination treatments for non-remitters at 12 weeks
- In total, about 70% of patients remitted
- No differences in order (sequencing) of treatment
- Currently analyzing 2-year recurrence rates (18 months after end of combination treatment)

Kennedy et al., 2017.

Striatal Serotonin Transporter (5-HTT) Occupancy in Depressed Subjects After 4 Weeks of Treatment at Minimum Therapeutic Doses of 5 SSRIs

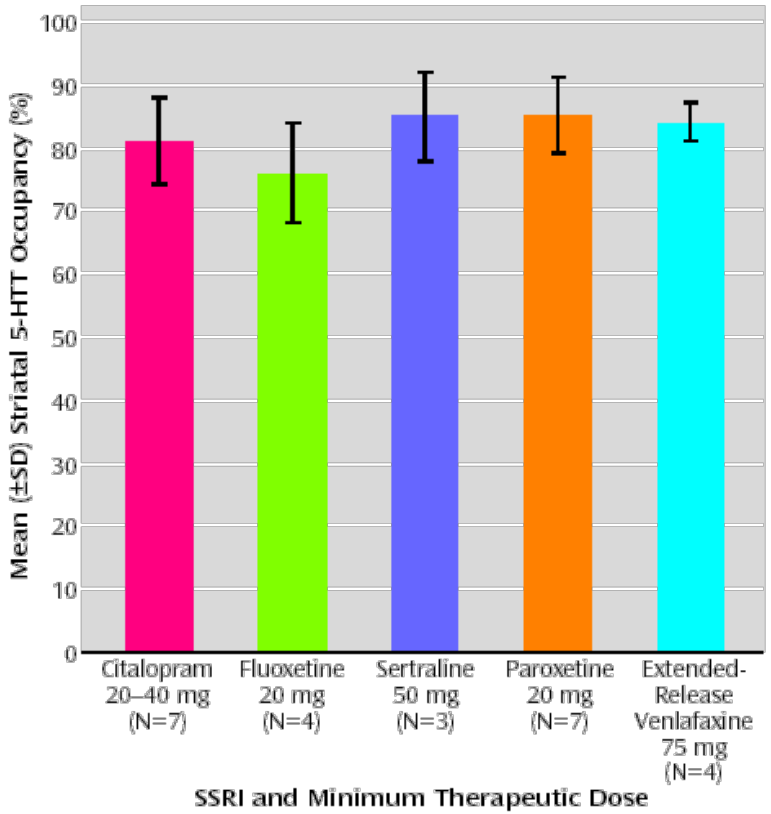


TABLE 1. Estimated Dose (ED_{50}) and Plasma Concentration (EC_{50}) Needed to Obtain 50% Serotonin Transporter Striatal Occupancy for Five SSRIs Administered to 77 Healthy and Depressed Subjects for 4 Weeks

SSRI	ED_{50} (mg/day)	EC_{50} (µg/liter)
Citalopram	3.4	11.7
Fluoxetine	2.7	14.8
Sertraline	9.1	1.1
Paroxetine	5.0	2.7
Extended-release venlafaxine	5.8	3.4

Meyer J, et al. *Am J Psychiatry*. 2004;161(5):826-835.

Potency of SSRIs

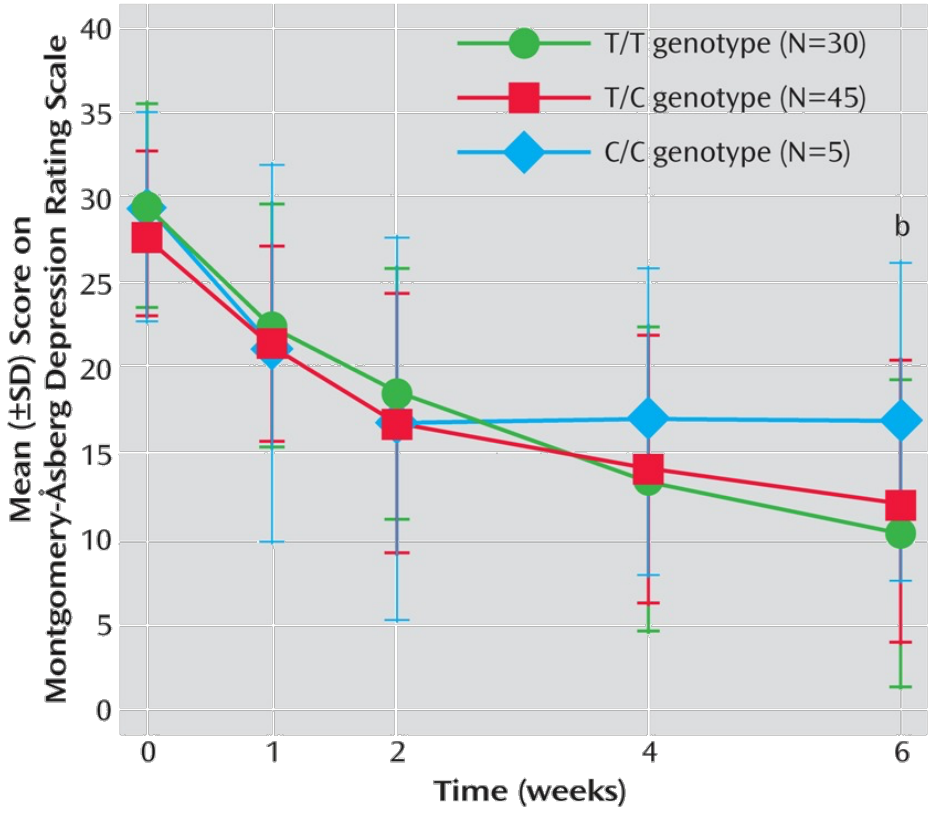
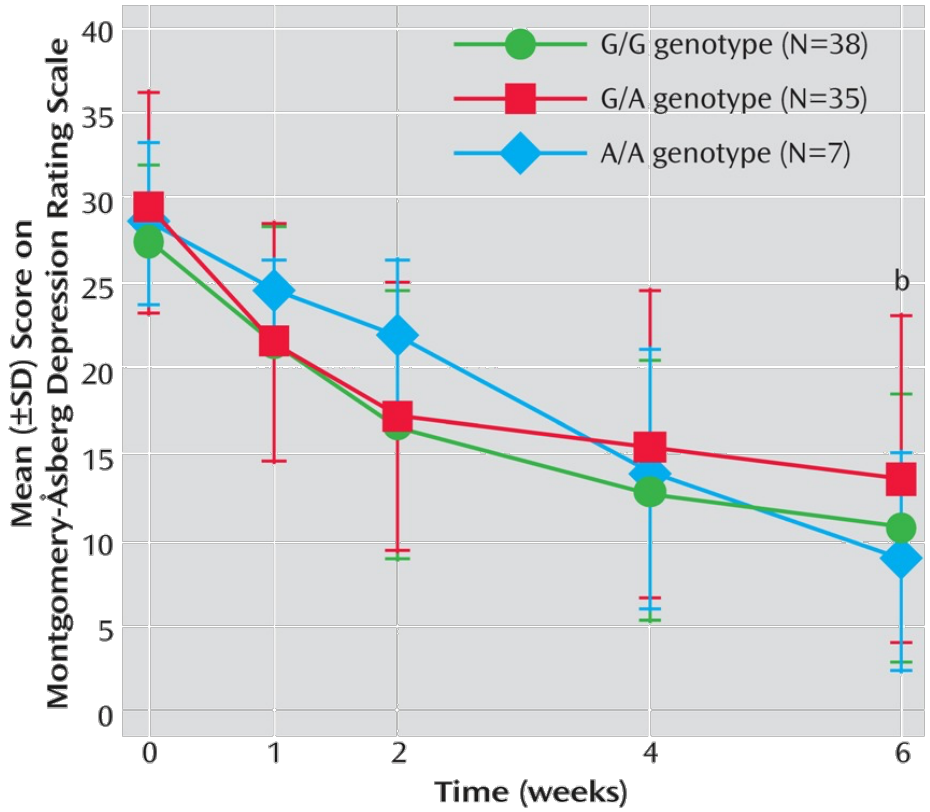
Montgomery-Åsberg Depression Scores During 6 Week Treatment in Relation to the NET T-128C Polymorphism



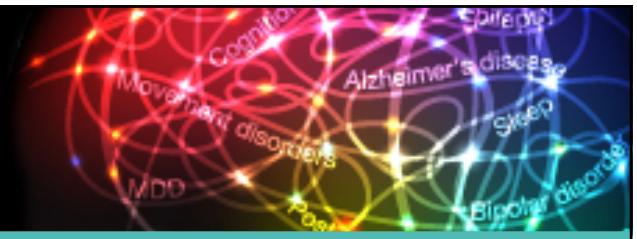
Yoshida K, et al. *Am J Psychiatry.* 2004:161:1575-1580.

Montgomery-Åsberg Depression Scores During 6 Week Treatment in Relation to the Polymorphism



Yoshida K, et al. *Am J Psychiatry*. 2004:161:1575-1580.

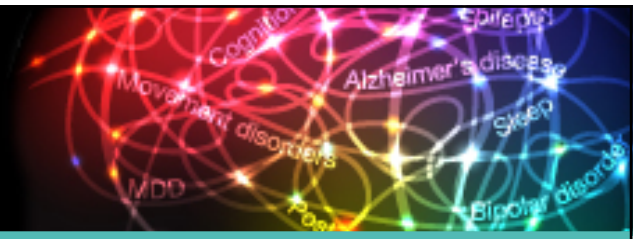
Objective and Method



- **Objective:** Investigate 5 putatively functional variants of the norepinephrine transporter (*SLC6A2, NET*) serotonin transporter (*SLC6A4, SERT*) genes and remission in depressed older adults treated with venlafaxine. Secondary objective was to analyze 17 other variants in serotonergic system genes (*HTR1A, HTR2A, HTR1B, HTR2C, TPH1, TPH2)* potential involved in the mechanisms of action of venlafaxine.
- **Methods:** 350 adults age 60 or older with *DSM-IV*-defined MDD and a score of at least 15 on the Montgomery-Asberg Depression Rating Scale (MADRS). Participants received protocolized treatment with open-label venlafaxine, up to 300 mg/day for approximately 12 weeks, as part of a 3-site clinical trial. Each individual was genotyped for 22 polymorphisms in 8 genes, which were tested for association with venlafaxine remission (MADRS score ≤ 10) and changes in MADRS score during treatment.

Marshe VS, et al. *Am J Psychiatry*. 2017;174:468-475.

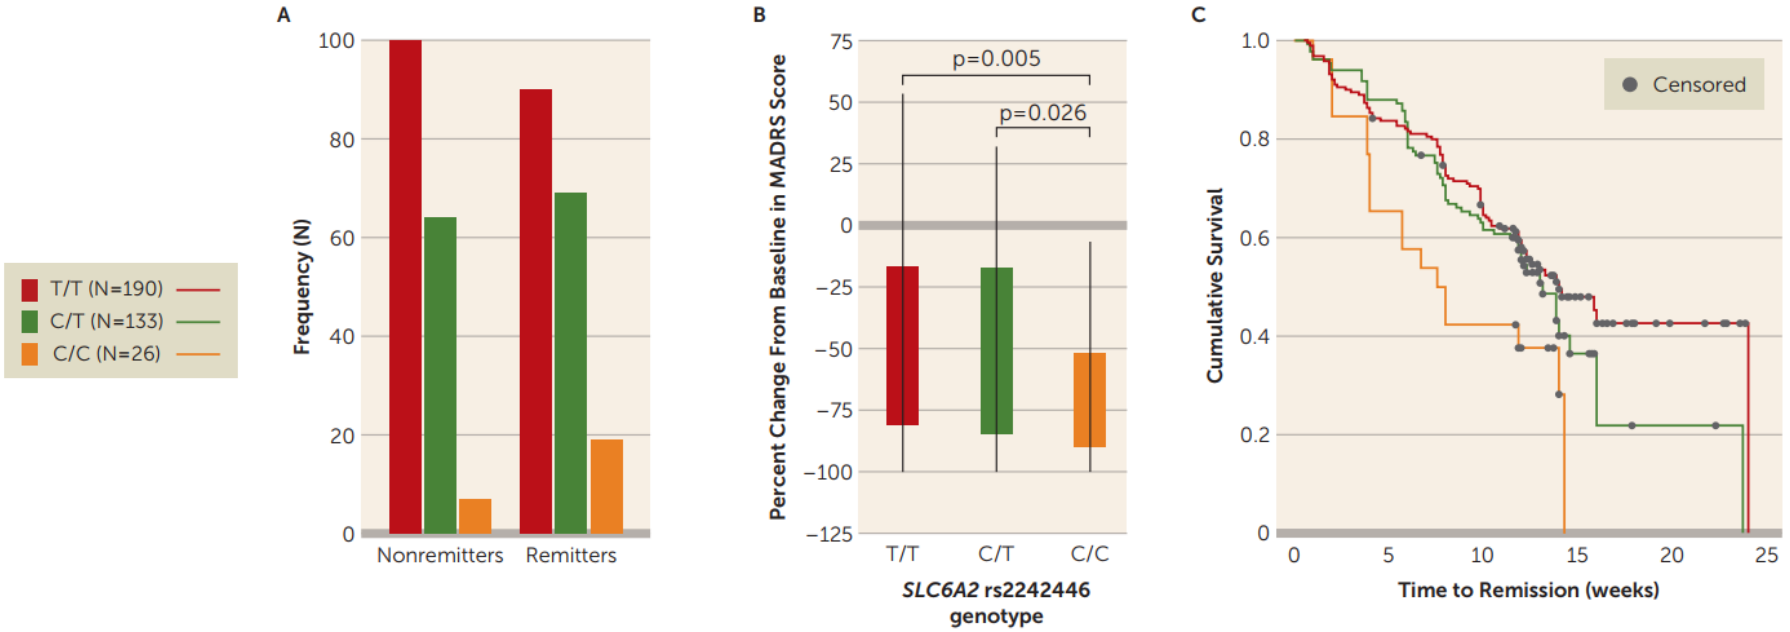
Results



- **Results:** After adjusting for multiple comparisons, *NET* variant rs2242446 (T-182C) was significantly associates with remission (odds ratio = 1.66, CI = 1.13, 2.42). Individuals with the rs2242446 C/C genotype were more likely to remit &73.1%) than those with either the C/T (51.8%) or the T/T genotype (47.3%). Individuals with the C/C genotype also had a shorter time to remission than those with the C/T or T/T genotypes and had a greater percentage change in MADRS score from baseline to end of treatment (up to week 12).

Marshe VS, et al. *Am J Psychiatry*. 2017;174:468-475.

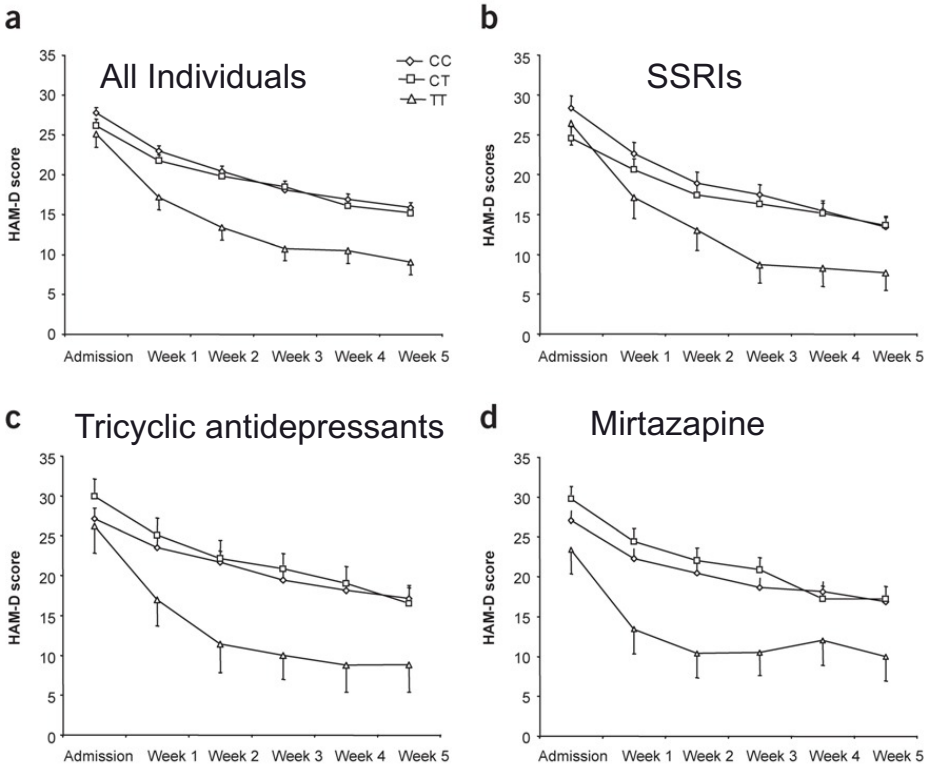
Association of *SCL6A2* Variant re2242446 with Remission, % Change from Baseline to End of Treatment in MADRS Score, and Time to Remission in the Total Sample (n = 350)



[a] In panel A, there was a significant association between remission status and *SLC6A2* rs2242446 genotype (odds ratio=1.67, 95% CI=1.13, 2.42, p=0.009). Panel B is a box-and-whisker plot showing the first quartile (25%, lower end), the median, and the third quartile (75%, upper end) for the variable percentage change in MADRS score. There was a significant association between percentage change in MADRS score and rs2242446 (partial eta squared, η^2=0.03, p=0.006). Panel C illustrates time to remission by rs2242446 status. There was a significant association between time to remission and rs2242446 (Mantel-Cox χ^2=9.47, df=2, p=0.009). MADRS=Montgomery-Åsberg Depression Rating Scale.

Marshe VS, et al. *Am J Psychiatry*. 2017;174:468-475.

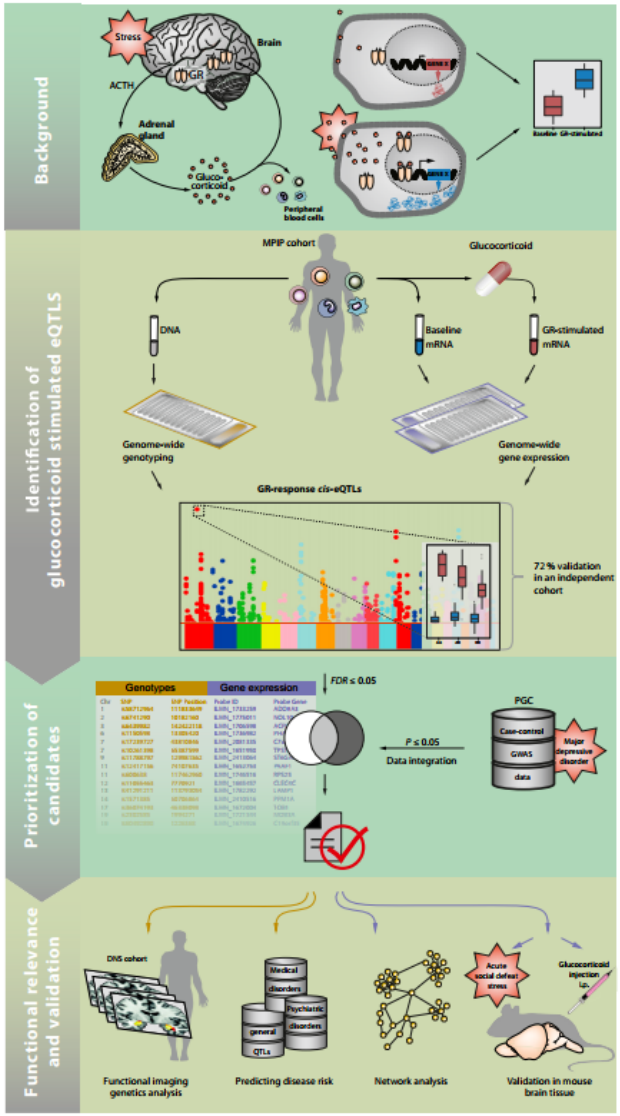
Polymorphisms in FKBP5 are Associated with Rapid Response to Antidepressant Treatment



Binder EB, et al. *Nature Genetics*. 2004;36(12):1319-1325.

Summary Figure Illustrating the Sequence of Experiments and Analyses

The main hypothesis tested in this study is that common genetic variants that after the short-term transcriptional response to GR activation also after the risk for stress-related psychiatric disorders and related neural endophenotypes.



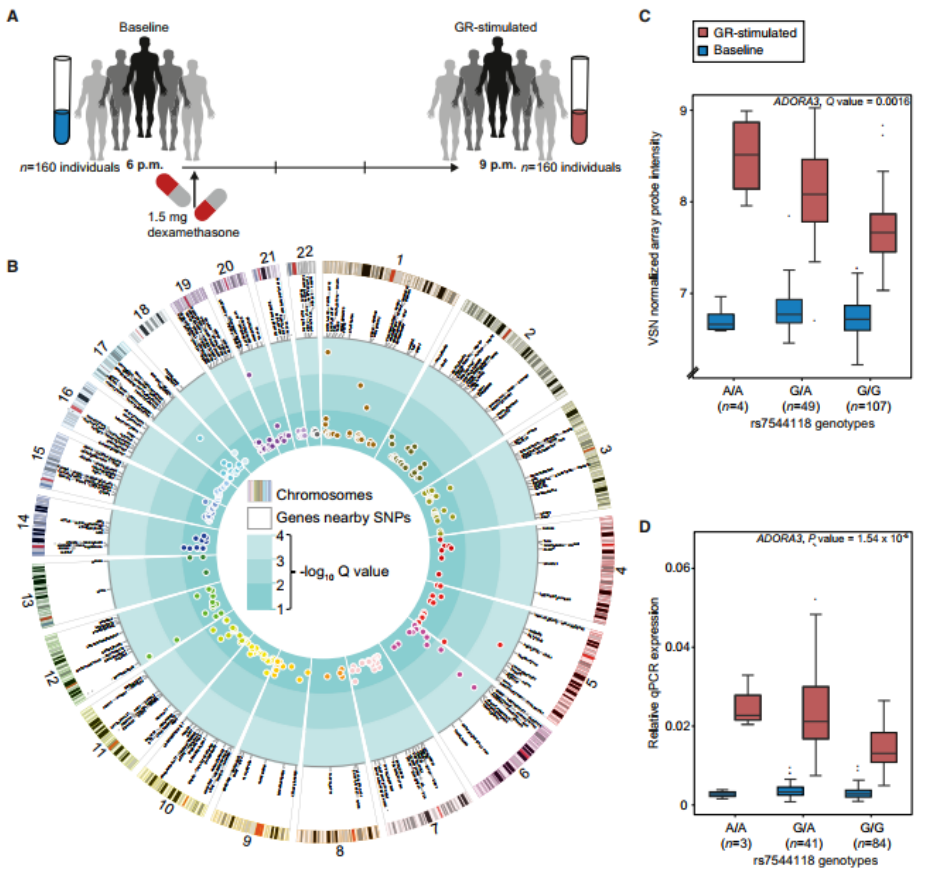
Arloth J, et al. *Neuron.* 2015;86(5):1189-1202.

GR-Response-Modulating *cis*-*e*QTLs

(A) Study design of GR-stimulated gene expression in whole blood of 160 male individuals from the Max Planck Institute of the Psychiatry cohort

(B) Circularized Manhattan plot displaying *cis*-associations for GR-response *e*QTL bins (n = 320) and their respective significance (-$\log_{10}$ Q values). Displayed from the outer to the inner circle are the number of chromosomes, the ideograms for the human karyotype (hg18), genes nearby *e*SNPs and Manhattan plot for the *e*QTL bins that survived correction for multiple testing.

(C and D) Boxplots of human gene expression values for *ADORA3.* Baseline (6 pm) measures are displayed in blue and GR-stimulated measures (9 pm) in red. Microarrays data are displayed in (C) and their *q*PCR validation in (D). Q value in (C) is derived from GR-response *cis*-*e*QTL analysis and the p value in (D) from the *q*PCR linear regression model.

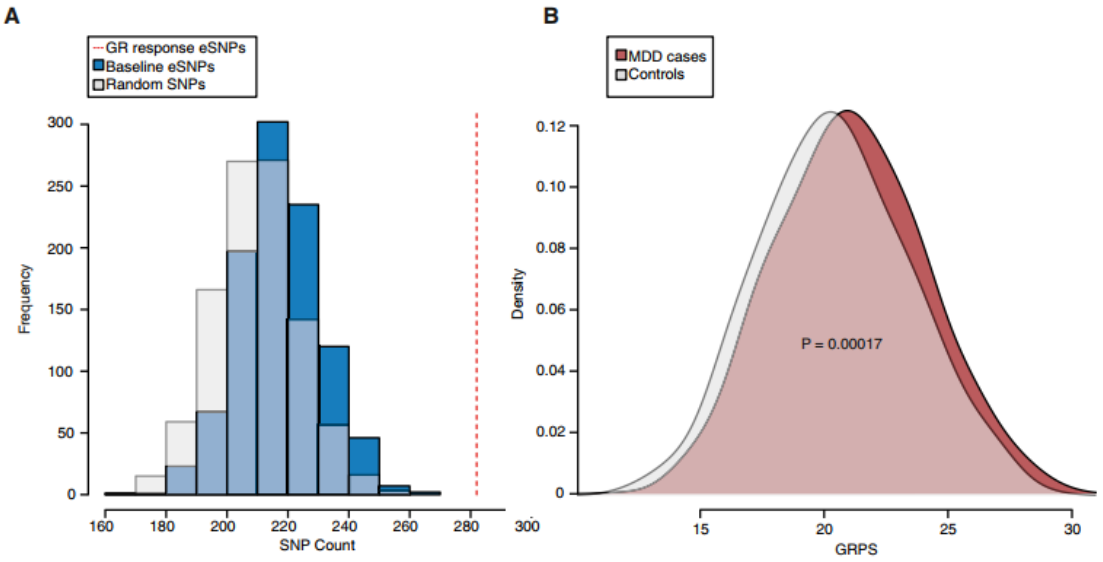


Arloth J, et al. *Neuron*. 2015;86(5):1189-1202.

GR-Response eSNPs are Enriched Among Variants Associated with MDD

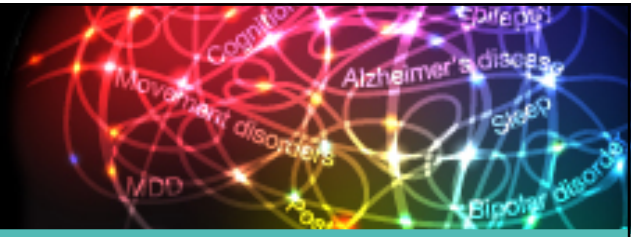
A. The dotted red line shows the enriched number of GR-response *e*SNPs that overlap with SNPs in our meta-analysis for MDD (= MDD-related GR *e*SNPs; 8,864 cases and 8,982 controls). The distribution of the observed overlap for sets of 1,000 random SNPs (gray) and 1,000 random baseline *e*SNPs (blue) are represented as histograms (null distributions). Both permuted data sets never reached the same overlap with MDD-associated SNPs as the GR-response *e*SNPs

B. The distribution of the MDD-related GR *e*SNPs genetic risk profile scores (GRPSs) for an independent sample of MDD cases (n = 1,005 cases; red) and controls (n = 478; gray) are represented as density plots. Individuals with MDD display higher GRPSs (p = 0.00017). P value by logistic regression model.



Arloth J, et al. *Neuron*. 2015;86(5):1189-1202.

Study Objective and Method



- **Objective**: The purpose was to inform the first-line treatment choice between CBT or an antidepressant medication for treatment-naïve adults with MDD by defining a neuroimaging biomarker that differentially identifies the outcomes of remission and treatment failure.
- **Method:** Functional MRI resting-state functional connectivity analyses using a bilateral subcallosal cingulate cortex (SCC) seed was applied to 122 patients from PReDICT study who completed 12 weeks of randomized treatment with CBT or antidepressant medication. Of the 122 participants, 58 achieved remission (HAM-D scored ≤ 7 at weeks 10 and 12), and 24 had treatment failure (< 30% decrease from baseline in HAM-D score). A 2 x 2 analysis of variance using voxel-wise subsampling permutation tests compared the interaction of treatment and outcomes. Receiver operating characteristic curves constructed using brain connectivity measures were used to determine possible classification rates for differential treatment outcomes.

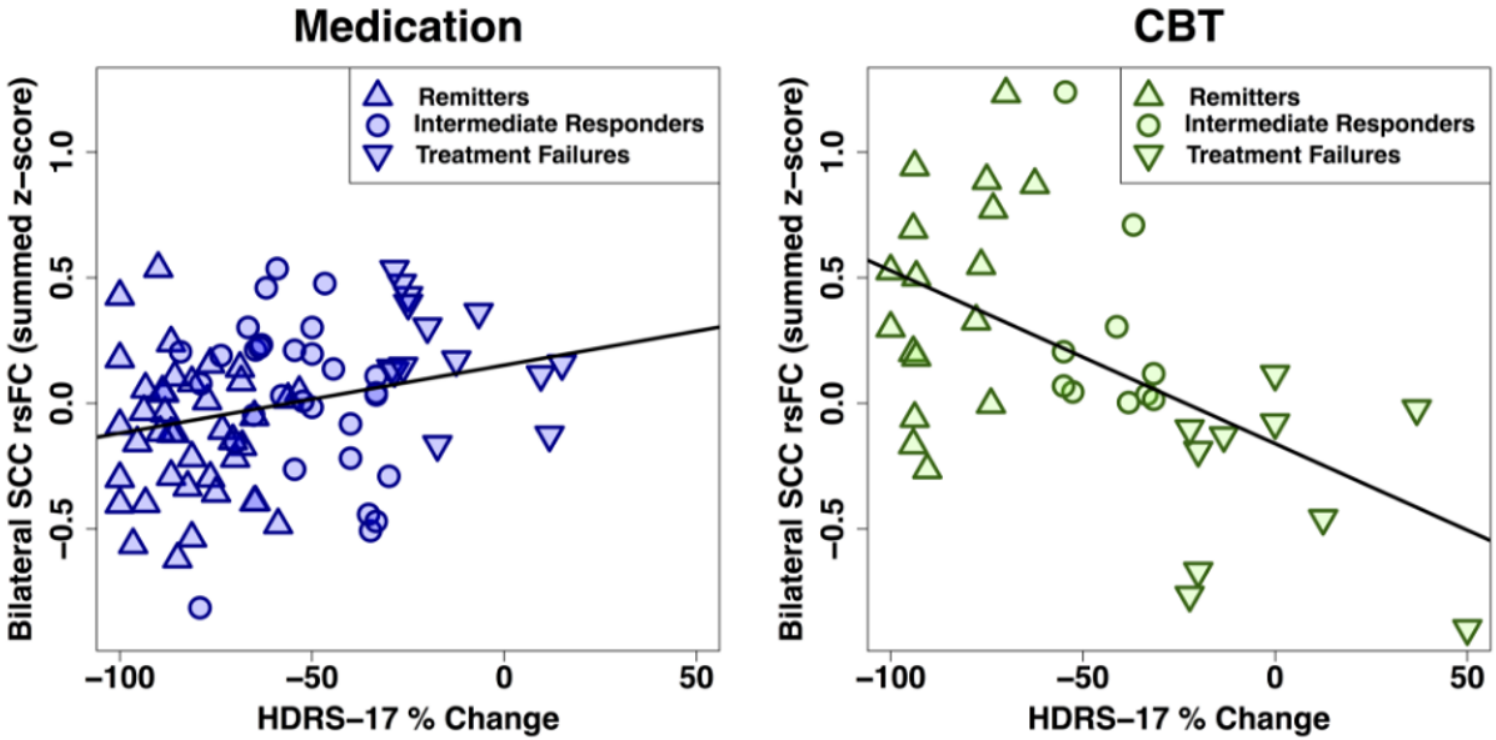
Dunlop BW, et al. *Am J Psychiatry*. 2017;174(6):533-545.

Results and Conclusions

- **Results:** Resting-stated functional connectivity of the following 3 regions with the SCC was differentially associated with outcomes of remission and treatment failure to CBT and antidepressant medication and survived application of the subsample permutation tests: dorsal midbrain, and left ventromedial prefrontal cortex. Using the summed SCC functional connectivity scores for these 3 regions, overall classification rates of 72%-78% for remission and 75%-89% for treatment failure was demonstrated. Positive summed functional connectivity was associated with remission with CBT and treatment failure with medication, whereas negative summed functional connectivity scores were associated with remission to medication and failure with CBT.
- **Conclusions**: Imaging-based depression subtypes defined using resting-state functional connectivity differentially identified an individual's probability of remission or treatment failure with first-line treatment options for MDD. This biomarker should be explored in future research through prospective testing and as a component of multivariate treatment prediction models.

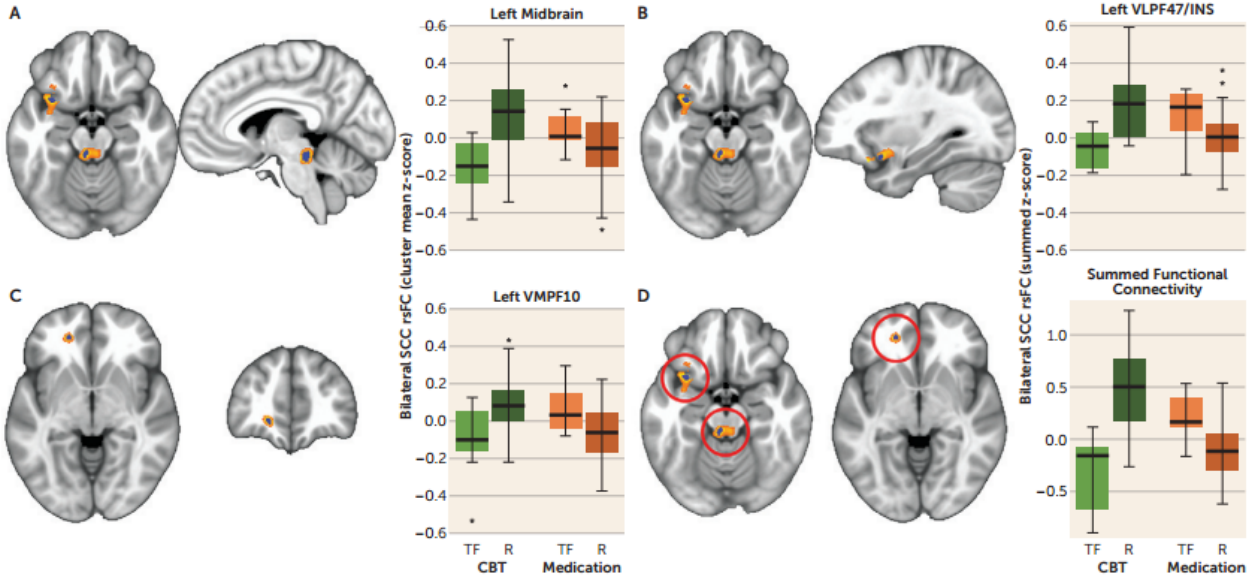
Dunlop BW, et al. *Am J Psychiatry*. 2017;174(6):533-545.

Medication vs. CBT



Dunlop BW, et al. *Am J Psychiatry*. 2017;174(6):533-545.

Differential Functional Connectivity of Subcallosal Cingulate Cortex Between Remitters and Treatment Failures With Antidepressant Medication or CBT[a]



[a] The figure shows A–C) the representative brain region and box plot of the z-score of the resting-state functional connectivity (rsFC) with the subcallosal cingulate cortex (SCC) between remitters (R) and treatment failures (TF) with each treatment type. The voxels identified by the subsample permutation testing (blue) are shown superimposed over voxels identified by the original analysis of variance (orange; see the Methods section in the article text). Box plots reflect contrasts using the permuted data. In all regions, the functional connectivity with the SCC seed is positive in CBT remitters and anticorrelated in CBT-treatment failures, whereas the inverse is true for antidepressant medication remitters and treatment failures. The images are as follows: A) dorsal midbrain; B) ventrolateral prefrontal cortex Brodmann area (BA) 47/insula (VLPF47/INS); C) ventromedial prefrontal cortex BA 10 (VMPF10); and D) box plots of the z-scores of the sum of the functional connectivity of the SCC with the three regions. The treatment-by-response interaction was significant at p=5e−10.

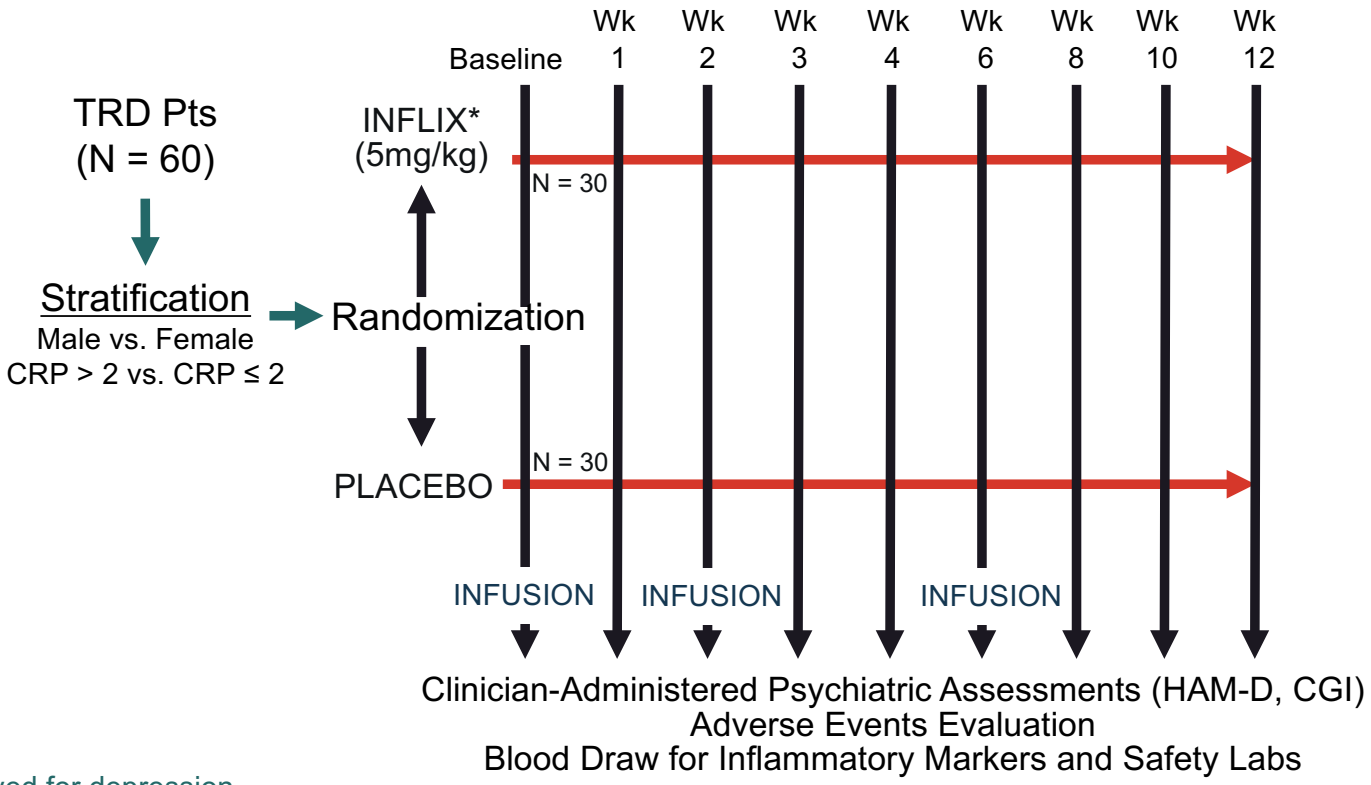
Basis for the Hypothesis that Inflammation and an Activated Innate Immune Response may Play a Role in Depression

- Patients with depression (both medically ill and medically healthy) have been found to exhibit all the cardinal features of inflammation.
  - increased peripheral blood and csf innate immune cytokines (IL-6 and TNF-alpha most reliable)
  - increased acute phase reactants (CRP most reliable)
  - increased chemokines
  - increased cellular adhesion molecules
- In the majority of studies, inflammatory markers decrease with successful antidepressant therapy ("state marker").

Double-Blind, Parallel-Group, Randomized Design



*Not FDA approved for depression

Raison CL, et al. *Arch Gen Psychiatry*. 2012;3:1-11.

Demographic Characteristics of Study Sample

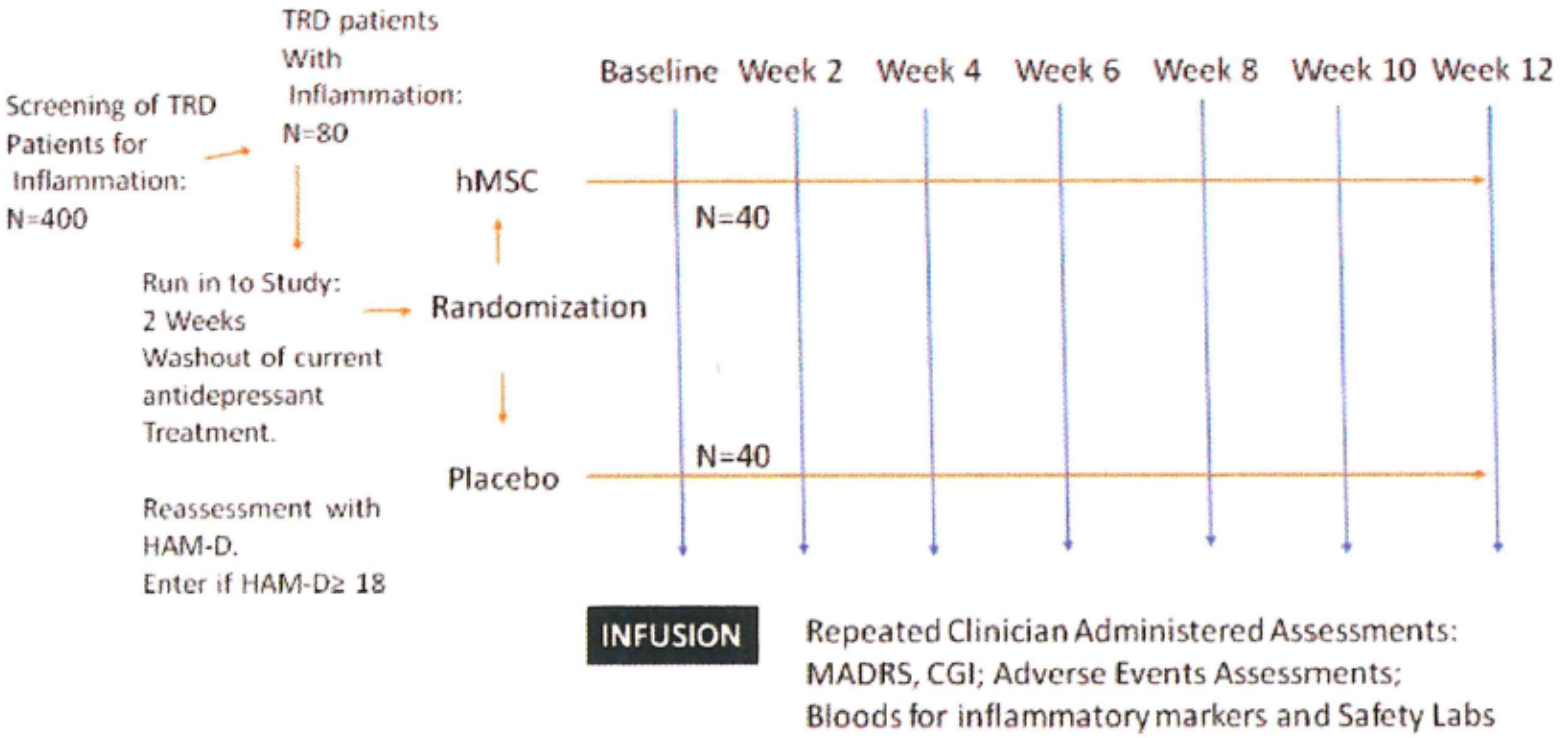
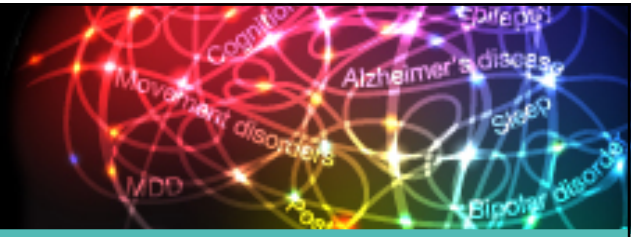
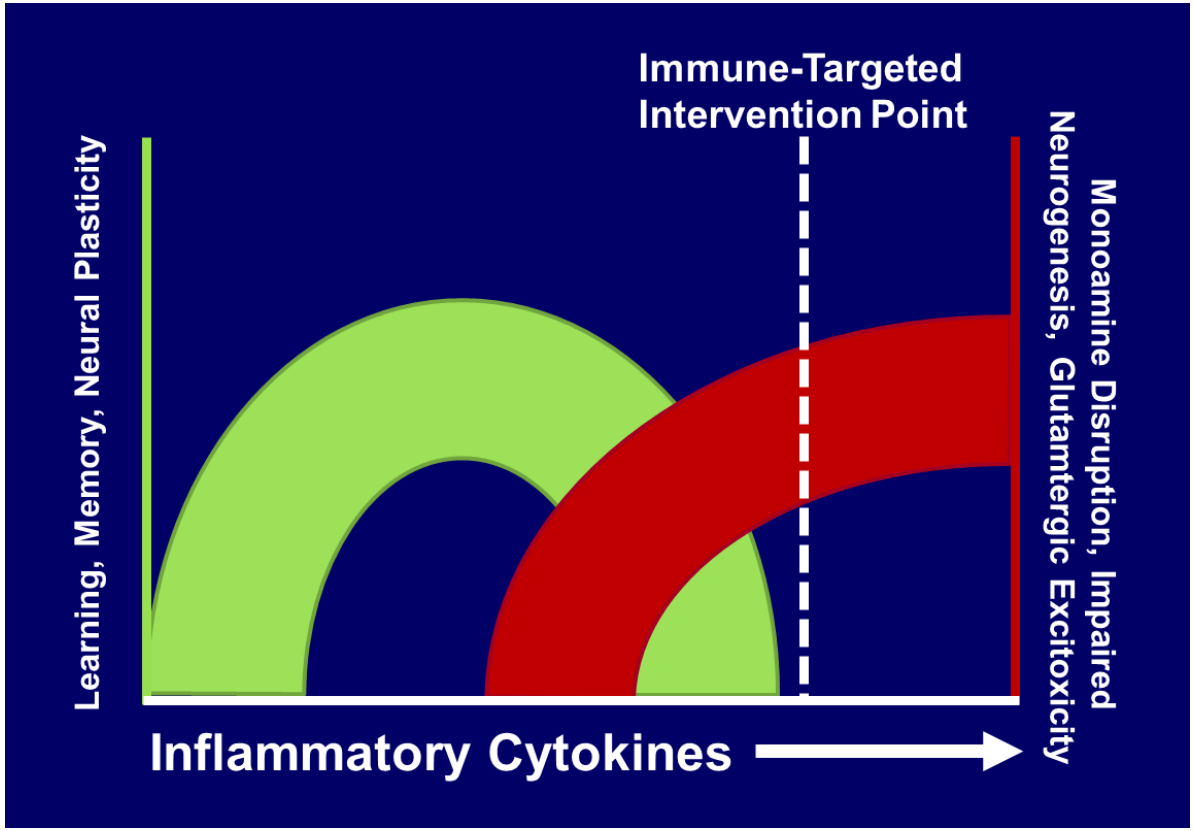
We propose the first study of mesenchymal stem cell therapy for the treatment of refractory depression.

Double-Blind Parallel Group Randomized Design



Hitting the Sweet Spot





Call to Action

- When evaluating a patient for major depression, make sure to get a thorough history to identify both genetic and environmental risk factors
- Engage patients in determining their preferred treatment plan as it may increase ability to achieve remission
